

CISC849 HW #3

For this assignment your team will implement a wall-following behavior using the lidar. Your program should allow the choice of a preferred wall side (left/right) as well as a desired lateral offset to be chosen at startup. Behaviors your robot should exhibit:

- (1) Start in free space, go straight until a blocking wall is encountered in front (at a distance that depends on chosen offset).
- (2) If the chosen side = left, make a right turn at this wall and move forward parallel to it at the chosen offset. If side = right, make a left turn and do the same
- (3) If a blocking wall is encountered in front, turn away from side wall and continue parallel to blocking wall.
- (4) If the side wall is "lost," turn toward that side until a wall is refound, then continue forward

You should not assume that all walls are straight or long, or that all turns are 90 degrees.

[RANSAC line-fitting](#) is 100% not necessary for this assignment but is something you can consider experimenting with after trying simpler approaches.

As a team

- First see Sep. 26 slides ("HW #3 prep") for some Github repos you should install
- As you did on HW #2, create a package. This time call it `<robot name>_cpp_laserfollow` or `<robot name>_py_laserfollow` depending on whether you are using [C++](#) or [Python](#). You might want to copy over some of your code from `wanderer` to `laserfollow`, because you should stop the robot if the bumper hazard is triggered at any time. As before, you will also be publishing `cmd_vel` messages to move the robot.
- New this time: you will be subscribing to the `/<robot name>/scan` topic (type [LaserScan](#)). In order to start the node that publishes these messages, you must:
 - a. `ssh` in to your robot's Raspberry Pi board (IP addresses are printed on the bulletin board by the door) with username `student` and password `<robot name>`.
 - b. After grounding yourself, plug in the blue USB cable on the robot to power up the lidar (make sure to unplug it when you are done!)

- c. Start up the lidar node on the Pi board:

```
ros2 run rplidar_ros rplidar_composition /scan:=/<robot
name>/scan --ros-args -p frame_id:=rplidar_link
```

- d. You should see something like this in your robot shell:

```
[INFO] [1678404921.927485908] [rplidar_node]: RPLIDAR running on ROS 2
package rplidar_ros. SDK Version: '1.12.0'
[INFO] [1678404924.439203400] [rplidar_node]: RPLIDAR S/N:
B793EDF9C7E29BCEA7E39EF227404304
[INFO] [1678404924.439449711] [rplidar_node]: Firmware Ver: 1.29
[INFO] [1678404924.439589023] [rplidar_node]: Hardware Rev: 7
[INFO] [1678404924.441306516] [rplidar_node]: RPLidar health status : '0'
[INFO] [1678404924.441455587] [rplidar_node]: Start
[INFO] [1678404924.985615468] [rplidar_node]: current scan mode:
Sensitivity, max_distance: 12.0 m, Point number: 7.9K , angle_compensate:
2, flip_x_axis 0
```

- e. Verify on your laptop that `/<robot name>/scan` messages are being published and that you can `echo` them

- f. Now see if you can visualize the `LaserScan` messages in `rviz2`. Your fixed frame should be `base_link`

- Now actually subscribe to the `LaserScan` messages in your `laserfollow` program and start developing your wall-following logic. The diagram below may be helpful in establishing a coordinate system if you want to convert the (r, θ) values in a `LaserScan` to (x, y) coordinates.

- In order to display your program state in `rviz2` while running, publish some kind of [Marker](#) shape or shapes that indicate which of the 4 states above is in effect.

Deliverables

Have one member of your team submit your code on Canvas along with a screen recording (or phone video of laptop screen) showing your robot in `rviz2` with lidar and markers overlaid doing as much of a circuit around the robot area perimeter as possible and a README file describing your approach (PDFs with simple explanatory figures welcome!).
