

## Introduction to NS-2:

- Widely known as NS2, is simply an event driven simulation tool.
- Useful in studying the dynamic nature of communication networks.
- Simulation of wired as well as wireless network functions and protocols (e.g., routing algorithms, TCP, UDP) can be done using NS2.
- In general, NS2 provides users with a way of specifying such network protocols and simulating their corresponding behaviors.

## Basic Architecture of NS2:

## Tcl scripting:

- Tcl is a general purpose scripting language. [Interpreter]
- Tcl runs on most of the platforms such as Unix, Windows, and Mac.
- The strength of Tcl is its simplicity.
- It is not necessary to declare a data type for variable prior to the usage.

## Basics of TCL:

Syntax: `command arg1 arg2 arg3`

### ● Hello World!

```
puts stdout{Hello, World!}
```

```
Hello, World!
```

### ● Variables Command Substitution

```
set a 5 set len [string length foobar]
```

```
set b $a set len [expr [string length foobar] + 9]
```

### ● Simple Arithmetic

```
expr 7.2 / 4
```

### ● Procedures

```
proc Diag {a b} {
  set c [expr sqrt($a * $a + $b * $b)]
  return $c }

```

puts "Diagonal of a 3, 4 right triangle is [Diag 3 4]"

Output: Diagonal of a 3, 4 right triangle is 5.0

### ● Loops

```
while {$i < $n} {
  ...
}
for {set i 0} {$i < $n} {incr i} {
  ...
}

```

### Wired TCL Script Components

- Create the event scheduler
- Open new files & turn on the tracing
- Create the nodes
- Setup the links
- Configure the traffic type (e.g., TCP, UDP, etc)
- Set the time of traffic generation (e.g., CBR, FTP)
- Terminate the simulation

### NS Simulator Preliminaries.

1. Initialization and termination aspects of the ns simulator.
2. Definition of network nodes, links, queues and topology.
3. Definition of agents and of applications.
4. The nam visualization tool.
5. Tracing and random variables.

### Initialization and Termination of TCL Script in NS-2:

An ns simulation starts with the command

```
set ns [new Simulator]
```

Which is thus the first line in the tcl script? This line declares a new variable as using the set command, you can call this variable as you wish, In general people declares it as ns because

it is an instance of the Simulator class, so an object the code[`new Simulator`] is indeed the installation of the class Simulator using the reserved word `new`.

In order to have output files with data on the simulation (trace files) or files used for visualization (nam files), we need to create the files using “open” command:

#### **#Open the Trace file**

```
set tracefile1 [open out.tr w]  
$ns trace-all $tracefile1
```

#### **#Open the NAM trace file**

```
set namfile [open out.nam w]  
$ns namtrace-all $namfile
```

The above creates a trace file called “out.tr” and a nam visualization trace file called “out.nam”. Within the tcl script, these files are not called explicitly by their names, but instead by pointers that are declared above and called “tracefile1” and “namfile” respectively. Remark that they begins with a # symbol. The second line open the file “out.tr” to be used for writing, declared with the letter “w”. The third line uses a simulator method called trace-all that have as parameter the name of the file where the traces will go.

The last line tells the simulator to record all simulation traces in NAM input format. It also gives the file name that the trace will be written to later by the command `$ns flush-trace`. In our case, this will be the file pointed at by the pointer “\$namfile”, i.e the file “out.tr”.

The termination of the program is done using a “finish” procedure.

#### **#Define a ‘finish’ procedure**

```
Proc finish { } {  
  global ns tracefile1  
  namfile  
  
  $ns flush-trace  
  
  Close $tracefile1  
  
  Close $namfile  
  
  Exec nam out.nam &  
  
  Exit 0  
}
```

The word `proc` declares a procedure in this case called **finish** and without arguments. The word **global** is used to tell that we are using variables declared outside the procedure. The simulator method “**flush-trace**” will dump the traces on the respective files. The `tcl` command “**close**” closes the trace files defined before and **exec** executes the `nam` program for visualization. The command **exit** will end the application and return the number 0 as status to the system. Zero is the default for a clean exit. Other values can be used to say that is a exit because something fails.

At the end of `ns` program we should call the procedure “**finish**” and specify at what time the termination should occur. For example,

```
$ns at 125.0 "finish"
```

will be used to call “**finish**” at time 125sec. Indeed, the **at** method of the simulator allows us to schedule events explicitly.

The simulation can then begin using the command

```
$ns run
```

### Definition of a network of links and nodes

The way to define a node is

```
set n0 [$ns  
node]
```

The node is created which is printed by the variable `n0`. When we shall refer to that node in the script we shall thus write `$n0`.

Once we define several nodes, we can define the links that connect them. An example of a definition of a link is:

```
$ns duplex-link $n0 $n2 10Mb 10ms DropTail
```

Which means that `$n0` and `$n2` are connected using a bi-directional link that has 10ms of propagation delay and a capacity of 10Mb per sec for each direction.

To define a directional link instead of a bi-directional one, we should replace “**duplex-link**” by “**simplex-link**”.

In NS, an output queue of a node is implemented as a part of each link whose input is that node. The definition of the link then includes the way to handle overflow at that queue. In our case, if the buffer capacity of the output queue is exceeded then the last packet to

arrive is dropped. Many alternative options exist, such as the RED (Random Early Discard) mechanism, the FQ (Fair Queuing), the DRR (Deficit Round Robin), the stochastic Fair Queuing (SFQ) and the CBQ (which including a priority and a round-robin scheduler).

In ns, an output queue of a node is implemented as a part of each link whose input is that node. We should also define the buffer capacity of the queue related to each link. An example would be:

```
#set Queue Size of link (n0-n2) to
20
$ns queue-limit $n0 $n2 20
```

### Agents and Applications

We need to define routing (sources, destinations) the agents (protocols) the application that use them.

### FTP over TCP:

TCP is a dynamic reliable congestion control protocol. It uses Acknowledgements created by the destination to know whether packets are well received.

There are number variants of the TCP protocol, such as Tahoe, Reno, NewReno, Vegas. The type of agent appears in the first line:

```
set tcp [new
Agent/TCP]
```

The command `$ns attach-agent $n0 $tcp` defines the source node of the tcp connection.

The command

```
set sink [new Agent
/TCPSink]
```

Defines the behavior of the destination node of TCP and assigns to it a pointer called sink.

### #Setup a UDP connection

```
set udp [new Agent/UDP]
$ns attach-agent $n1 $udp
set null [new Agent/Null]
$ns attach-agent $n5 $null
$ns connect $udp $null
$udp set fid_2
```

**#setup a CBR over UDP connection**

```
set cbr [new
Application/Traffic/CBR]
$cbr attach-agent $udp
$cbr set packetSize_ 100
$cbr set rate_ 0.01Mb
$cbr set random_ false
```

Above shows the definition of a CBR application using a UDP agent

The command **\$ns attach-agent \$n4 \$sink** defines the destination node. The command **\$ns connect \$tcp \$sink** finally makes the TCP connection between the source and destination nodes.

TCP has many parameters with initial fixed defaults values that can be changed if mentioned explicitly. For example, the default TCP packet size has a size of 1000bytes. This can be changed to another value, say 552bytes, using the command **\$tcp set packetSize\_ 552**.

When we have several flows, we may wish to distinguish them so that we can identify them with different colors in the visualization part. This is done by the command **\$tcp set fid\_ 1** that assigns to the TCP connection a flow identification of “1”. We shall later give the flow identification of “2” to the UDP connection.

**CBR over UDP**

A UDP source and destination is defined in a similar way as in the case of TCP.

Instead of defining the rate in the command **\$cbr set rate\_ 0.01Mb**, one can define the time interval between transmission of packets using the command.

```
$cbr set interval_
0.005
```

The packet size can be set to some value using

```
$cbr set packetSize_ <packet
size>
```

### Scheduling Events

NS is a discrete event based simulation. The tcp script defines when event should occur. The initializing command set ns [new Simulator] creates an event scheduler, and events are then scheduled using the format:

```
$ns at <time> <event>
```

The scheduler is started when running ns that is through the command \$ns run.

The beginning and end of the FTP and CBR application can be done through the following command

```
$ns at 0.1 "$cbr start"
$ns at 1.0 "$ftp start"
$ns at 124.0 "$ftp
stop"
$ns at 124.5 "$cbr
stop"
```

### Structure of Trace Files:

When tracing into an output ASCII file, the trace is organized in 12 fields as follows in fig shown below, The meaning of the fields are:

Event	Time	From Node	To Node	PKT Type	PKT Size	Flags	Fid	Src Addr	Dest Addr	Seq Num	Pkt id
-------	------	--------------	------------	-------------	-------------	-------	-----	-------------	--------------	------------	-----------

1. The first field is the event type. It is given by one of four possible symbols r, +, -, d which correspond respectively to receive (at the output of the link), enqueued, dequeued and dropped.
2. The second field gives the time at which the event occurs.
3. Gives the input node of the link at which the event occurs.
4. Gives the output node of the link at which the event occurs.
5. Gives the packet type (eg CBR or TCP)

6. Gives the packet size
7. Some flags
8. This is the flow id (fid) of IPv6 that a user can set for each flow at the input OTcl script one can further use this field for analysis purposes; it is also used when specifying stream color for the NAM display.
9. This is the source address given in the form of “node.port”.
10. This is the destination address, given in the same form.
11. This is the network layer protocol’s packet sequence number. Even though UDP implementations in a real network do not use sequence number, ns keeps track of UDP packet sequence number for analysis purposes
12. The last field shows the Unique id of the packet.

## **XGRAPH**

The xgraph program draws a graph on an x-display given data read from either data file or from standard input if no files are specified. It can display upto 64 independent data sets using different colors and line styles for each set. It annotates the graph with a title, axis labels, grid lines or tick marks, grid labels and a legend.

### **Syntax:**

<b>Xgraph</b> <b>[options]</b> <b>file-name</b>
--

Options are listed here

#### **/-bd <color> (Border)**

This specifies the border color of the xgraph window.

#### **/-bg <color> (Background)**

This specifies the background color of the xgraph window.

#### **/-fg<color> (Foreground)**

This specifies the foreground color of the xgraph window.

#### **/-lf <fontname> (LabelFont)**

All axis labels and grid labels are drawn using this font.

#### **/-t<string> (Title Text)**

This string is centered at the top of the graph.

#### **/-x <unit name> (XunitText)**

This is the unit name for the x-axis. Its default is "X".

#### **/-y <unit name> (YunitText)**

This is the unit name for the y-axis. Its default is "Y".

### Awk- An Advanced

Awk is a programmable, pattern-matching, and processing tool available in UNIX. It works equally well with text and numbers.

Awk is not just a command, but a programming language too. In other words, awk utility is a pattern scanning and processing language. It searches one or more files to see if they contain lines that match specified patterns and then perform associated actions, such as writing the line to the standard output or incrementing a counter each time it finds a match.

Syntax:

```
awk option 'selection_criteria {action}'
file(s)
```

Here, selection\_criteria filters input and select lines for the action component to act upon. The selection\_criteria is enclosed within single quotes and the action within the curly braces. Both the selection\_criteria and action forms an awk program.

**Example: \$ awk '/manager/ {print}' emp.lst**

#### Variables

Awk allows the user to use variables of their choice. You can now print a serial number, using the variable kount, and apply it those directors drawing a salary exceeding 6700:

```
$ awk -F"|" ' $3 == "director" && $6 > 6700 {
kount =kount+1
printf " %3f %20s %-12s %d\n", kount,$2,$3,$6 }' empn.lst
```

#### THE -f OPTION: STORING awk PROGRAMS IN A FILE

You should hold large awk programs in separate file and provide them with the awk extension for easier identification. Let's first store the previous program in the file empawk.awk:

```
$ cat empawk.awk
```

Observe that this time we haven't used quotes to enclose the awk program. You can now use awk with the `-f filename` option to obtain the same output:

```
Awk -F'|' -f empawk.awk empn.lst
```

### **THE BEGIN AND END SECTIONS:**

Awk statements are usually applied to all lines selected by the address, and if there are no addresses, then they are applied to every line of input. But, if you have to print something before processing the first line, for example, a heading, then the BEGIN section can be used gainfully. Similarly, the end section useful in printing some totals after processing is over.

The BEGIN and END sections are optional and take the form

```
BEGIN {action}
```

```
END {action}
```

These two sections, when present, are delimited by the body of the awk program. You can use them to print a suitable heading at the beginning and the average salary at the end.

### **BUILT-IN VARIABLES:**

Awk has several built-in variables. They are all assigned automatically, though it is also possible for a user to reassign some of them. You have already used NR, which signifies the record number of the current line. We'll now have a brief look at some of the other variable.

**The FS Variable:** as stated elsewhere, awk uses a contiguous string of spaces as the default field delimiter. FS redefines this field separator, which in the sample database happens to be the |. When used at all, it must occur in the BEGIN section so that the body of the program knows its value before it starts processing:

```
BEGIN {FS="|"}
```

This is an alternative to the `-F` option which does the same thing.

**The OFS Variable:** when you used the print statement with comma-separated arguments, each argument was separated from the other by a space. This is awk's default output field separator, and can be reassigned using the variable OFS in the BEGIN section:

---

```
BEGIN { OFS="~" }
```

When you reassign this variable with a ~ (tilde), awk will use this character for delimiting the print arguments. This is a useful variable for creating lines with delimited fields.

*The NF variable:* NF comes in quite handy for cleaning up a database of lines that don't contain the right number of fields. By using it on a file, say emp.lst, you can locate those lines not having 6 fields, and which have crept in due to faulty data entry:

```
$awk 'BEGIN {FS = "|"}'
```

```
NF! =6 {
```

```
Print "Record No ", NR, "has", "fields"}' emp.lst
```

**Date:**

### THREE NODE POINT TO POINT NETWORK

*Aim: Implement three nodes point – to – point network with duplex links between them for different topologies. Set the queue size, vary the bandwidth and find the number of packets dropped for various iterations.*

```
set ns [new Simulator]                # Letter S is capital
set nf [open lab1.nam w]              # open a nam trace file in write mode
$ns namtrace-all $nf                 # nf nam filename
set tf [open lab1.tr w]                # tf trace filename
$ns trace-all $tf

proc finish { } {
    global ns nf tf
    $ns flush-trace                      # clears trace file contents
    close $nf
    close $tf
    exec nam lab1.nam &
    exit 0
}
set n0 [$ns node]                      # creates 3 nodes
set n2 [$ns node]
set n3 [$ns node]

$ns duplex-link $n0 $n2 200Mb 10ms DropTail # establishing links
$ns duplex-link $n2 $n3 1Mb 1000ms DropTail
$ns queue-limit $n0 $n2 10

set udp0 [new Agent/UDP]                # attaching transport layer protocols
$ns attach-agent $n0 $udp0
set cbr0 [new Application/Traffic/CBR]   # attaching application layer protocols
```

```

$scr0 set packetSize_ 500
$scr0 set interval_ 0.005
$scr0 attach-agent $udp0

```

```

set null0 [new Agent/Null] # creating sink(destination) node
$ns attach-agent $n3 $null0
$ns connect $udp0 $null0

```

```

$ns at 0.1 "$scr0 start"
$ns at 1.0 "finish"
$ns run

```

**AWK file:** (Open a new editor using “vi command” and write awk file and save with “.awk” extension)

#immediately after BEGIN should open braces ‘{‘

```

BEGIN{ c=0;}
{
  if($1=="d")
  {
    c++;
    printf("%s\t%s\n",$5,$11);
  }
}
END{ printf("The number of packets dropped is %d\n",c); }

```

### Steps for execution

- Open gedit editor and type program. Program name should have the extension “.tcl ”

```
[root@localhost ~]# gedit lab1.tcl
```

- Save the program and close the file.
- Open gedit editor and type awk program. Program name should have the extension “.awk ”

```
[root@localhost ~]# gedit lab1.awk
```

- Save the program and close the file.
- Run the simulation program
- Here “ns” indicates network simulator. We get the topology shown in the snapshot.
- Now press the play button in the simulation window and the simulation will begins.

```
[root@localhost~]# ns lab1.tcl
```

- After simulation is completed run awk file to see the output ,

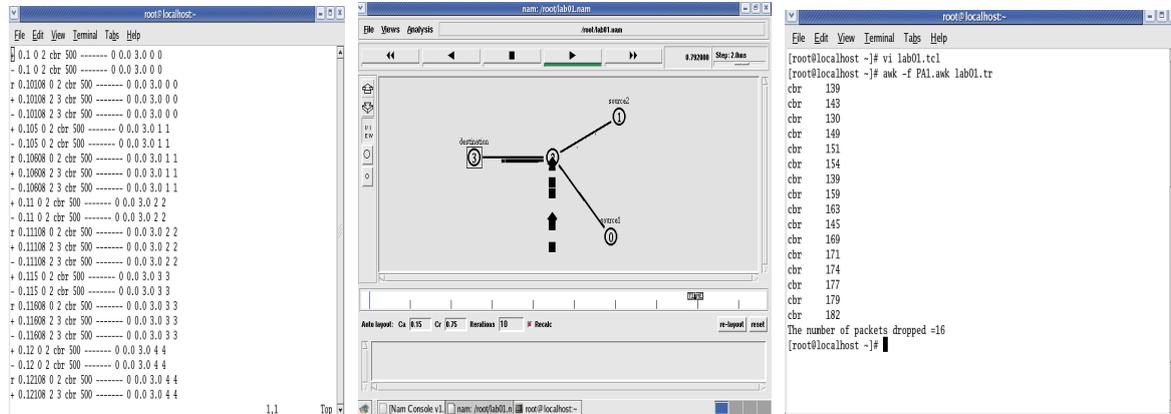

```
[root@localhost~]# awk -f lab1.awk lab1.tr
```

- To see the trace file contents open the file as ,

```
[root@localhost~]# gedit lab1.tr
```

**Trace file contains 12 columns:**

*Event type, Event time, From Node, To Node, Packet Type, Packet Size, Flags (indicated by -----), Flow ID, Source address, Destination address, Sequence ID, Packet ID*

Contents of Trace File

Topology

Output

**Experiment No: 2****Date:****SIMPLE ESS WITH WIRELESS LAN**

***Aim: Implement simple ESS and with transmitting nodes in wire-less LAN by simulation and determine the throughput (performance) with respect to transmission of packets.***

    if($1=="r"&& $3=="_1_" && $4=="AGT")
    {
        count1++
        pack1=pack1+$8
        time1=$2
    }
    if($1=="r" && $3=="_2_" && $4=="AGT")
    {
        count2++
        pack2=pack2+$8
        time2=$2
    }
}

END{
printf("The Throughput from n0 to n1: %f Mbps \n", ((count1*pack1*8)/(time1*1000000)));
printf("The Throughput from n1 to n2: %f Mbps", ((count2*pack2*8)/(time2*1000000)));
}

```

### **Steps for execution**

- Open gedit editor and type program. Program name should have the extension “.tcl”

***[root@localhost ~]# gedit lab4.tcl***

- Save the program and close the file.
- Open gedit editor and type **awk** program. Program name should have the extension “.awk”

***[root@localhost ~]# gedit lab4.awk***

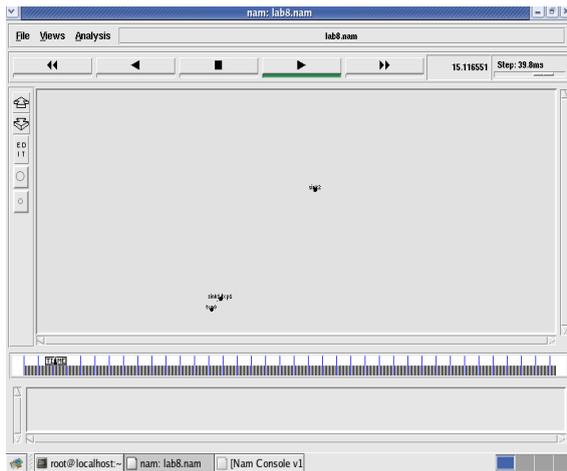

- Save the program and close the file.
- Run the simulation program

***[root@localhost~]# ns lab4.tcl***

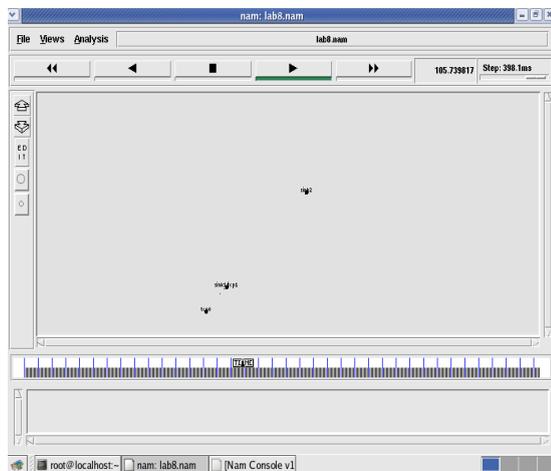

- Here “**ns**” indicates network simulator. We get the topology shown in the snapshot.

- Now press the play button in the simulation window and the simulation will begin.
- After simulation is completed run **awk file** to see the output ,  
**[root@localhost~]# awk -f lab4.awk lab4.tr**
- To see the trace file contents open the file as ,  
**[root@localhost~]# gedit lab4.tr**

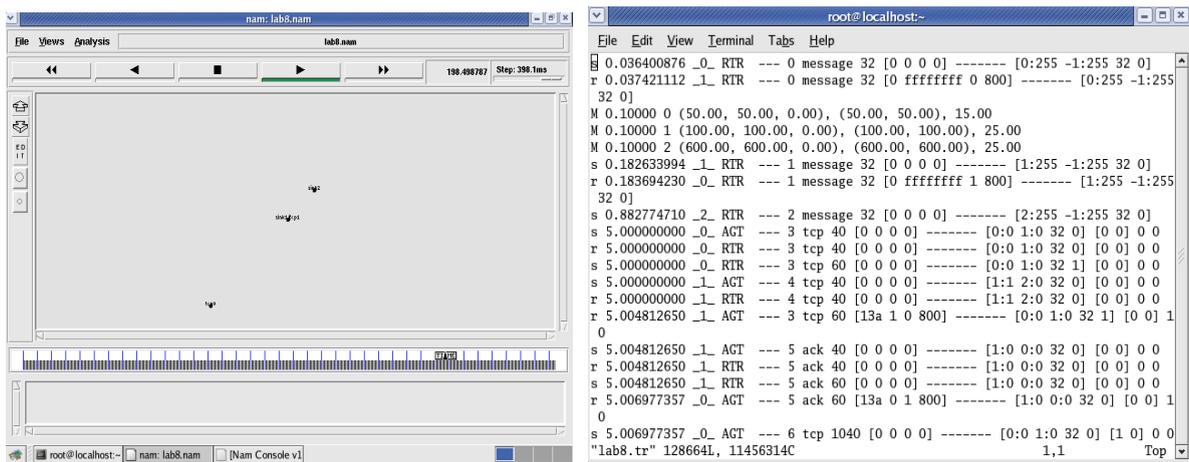

### Output:

Node 1 and 2 are communicating

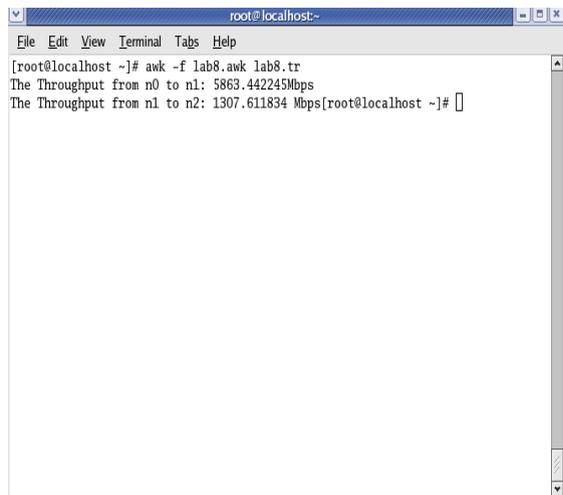

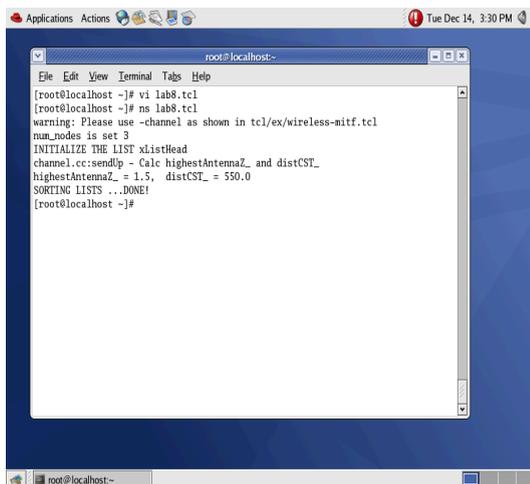

Node 2 is moving towards node 3

Node 2 is coming back from node 3 towards node1

Trace File

Here “M” indicates mobile nodes, “AGT” indicates Agent Trace, “RTR” indicates Route Trace

**Experiment No: 3****Date:****Error Detecting Code Using CRC-CCITT (16-bits)*****Aim: Write a Program for ERROR detecting code using CRC-CCITT (16bit).***

Whenever digital data is stored or interfaced, data corruption might occur. Since the beginning of computer science, developers have been thinking of ways to deal with this type of problem. For serial data they came up with the solution to attach a parity bit to each sent byte. This simple detection mechanism works if an odd number of bits in a byte changes, but an even number of false bits in one byte will not be detected by the parity check. To overcome this problem developers have searched for mathematical sound mechanisms to detect multiple false bits. The **CRC** calculation or *cyclic redundancy check* was the result of this. Nowadays CRC calculations are used in all types of communications. All packets sent over a network connection are checked with a CRC. Also each data block on your hard disk has a CRC value attached to it. Modern computer world cannot do without these CRC calculations. So let's see why they are so widely used. The answer is simple; they are powerful, detect many types of errors and are extremely fast to calculate especially when dedicated hardware chips are used.

$$\begin{array}{r}
 \phantom{10011} / 1101101 \\
 \underline{10011} \phantom{00} \\
 100000 \\
 \phantom{100000} \phantom{00} \\
 \underline{10000} \phantom{0} \\
 10011 \\
 \underline{\phantom{10011}0} \\
 1110 = 14 = \text{remainder}
 \end{array}$$

The idea behind CRC calculation is to look at the data as one large binary number. This number is divided by a certain value and the remainder of the calculation is called the CRC. Dividing in the CRC calculation at first looks to cost a lot of computing power, but it can be performed very quickly if we use a method similar to the one learned at school. We will as an example calculate the remainder for the character 'm'—which is 1101101 in binary notation—by dividing it by 19 or 10011. Please note that 19 is an odd number. This is necessary as we will see further on. Please refer to your schoolbooks as the binary calculation

method here is not very different from the decimal method you learned when you were young. It might only look a little bit strange. Also notations differ between countries, but the method is similar.

With decimal calculations you can quickly check that 109 divided by 19 gives a quotient of 5 with 14 as the remainder. But what we also see in the scheme is that every bit extra to check only costs one binary comparison and in 50% of the cases one binary subtraction. You can easily increase the number of bits of the test data string—for example to 56 bits if we use our example value "*Lammert*"—and the result can be calculated with 56 binary comparisons and an average of 28 binary subtractions. This can be implemented in hardware directly with only very few transistors involved. Also software algorithms can be very efficient.

All of the CRC formulas you will encounter are simply checksum algorithms based on modulo-2 binary division where we ignore carry bits and in effect the subtraction will be equal to an *exclusive or* operation. Though some differences exist in the specifics across different CRC formulas, the basic mathematical process is always the same:

- The message bits are appended with  $c$  zero bits; this *augmented message* is the dividend
- A predetermined  $c+1$ -bit binary sequence, called the *generator polynomial*, is the divisor
- The checksum is the  $c$ -bit remainder that results from the division operation

Table 1 lists some of the most commonly used generator polynomials for 16- and 32-bit CRCs. Remember that the width of the divisor is always one bit wider than the remainder. So, for example, you'd use a 17-bit generator polynomial whenever a 16-bit checksum is required.

*Table 1: International Standard CRC Polynomials*

	<b>CRC-CCITT</b>	<b>CRC-16</b>	<b>CRC-32</b>
Checksum Width	16 bits	16 bits	32 bits
Generator Polynomial	10001000000100001	11000000000000101	100000100110000010001110110110111

**Error detection with CRC**

Consider a message represented by the polynomial  $M(x)$

Consider a *generating polynomial*  $G(x)$

This is used to generate a CRC =  $C(x)$  to be appended to  $M(x)$ .

Note this  $G(x)$  is prime.

Steps:

1. Multiply  $M(x)$  by highest power in  $G(x)$ . i.e. Add So much zeros to  $M(x)$ .
2. Divide the result by  $G(x)$ . The remainder =  $C(x)$ .  
Special case: This won't work if bitstring =all zeros. We don't allow such an  $M(x)$ . But  $M(x)$  bitstring = 1 will work, for example. Can divide 1101 into 1000.
3. If:  $x \text{ div } y$  gives remainder  $c$   
that means:  $x = n y + c$   
Hence  $(x-c) = n y$   
 $(x-c) \text{ div } y$  gives remainder 0  
Here  $(x-c) = (x+c)$   
Hence  $(x+c) \text{ div } y$  gives remainder 0
4. Transmit:  $T(x) = M(x) + C(x)$
5. Receiver end: Receive  $T(x)$ . Divide by  $G(x)$ , should have remainder 0.

**Note if  $G(x)$  has order  $n$  - highest power is  $x^n$ ,  
then  $G(x)$  will cover  $(n+1)$  bits  
and the *remainder* will cover  $n$  bits.  
i.e. Add  $n$  bits (Zeros) to message.**

**Some CRC polynomials that are actually used**

Some CRC polynomials

- CRC-8:  
 $x^8+x^2+x+1$ 
  - Used in: 802.16 (along with error *correction*).
- CRC-CCITT:  
 $x^{16}+x^{12}+x^5+1$

- o Used in: HDLC, SDLC, PPP default
- IBM-CRC-16 (ANSI):  
 $x^{16}+x^{15}+x^2+1$
- 802.3:  
 $x^{32}+x^{26}+x^{23}+x^{22} +x^{16}+x^{12}+x^{11}+x^{10} +x^8+x^7+x^5+x^4+x^2+x+1$
- o Used in: Ethernet, PPP rootion

**Source Code:**

- To see the trace file contents open the file as ,

**[root@localhost~]# gedit lab2.tr**

**Experiment No: 5****Date:****BELLMAN-FORD ALGORITHM**

*Aim: Write a program to find the shortest path between vertices using bellman-ford algorithm.*

Distance Vector Algorithm is a decentralized routing algorithm that requires that each router simply inform its neighbors of its routing table. For each network path, the receiving routers pick the neighbor advertising the lowest cost, then add this entry into its routing table for re-advertisement. To find the shortest path, Distance Vector Algorithm is based on one of two basic algorithms: the Bellman-Ford and the Dijkstra algorithms.

Routers that use this algorithm have to maintain the distance tables (which is a one-dimension array -- "a vector"), which tell the distances and shortest path to sending packets to each node in the network. The information in the distance table is always up'd by exchanging information with the neighboring nodes. The number of data in the table equals to that of all nodes in networks (excluded itself). The columns of table represent the directly attached neighbors whereas the rows represent all destinations in the network. Each data contains the path for sending packets to each destination in the network and distance/or time to transmit on that path (we call this as "cost"). The measurements in this algorithm are the number of hops, latency, the number of outgoing packets, etc.\

The Bellman-Ford algorithm is an algorithm that computes shortest paths from a single source vertex to all of the other vertices in a weighted digraph. It is slower than Dijkstra's algorithm for the same problem, but more versatile, as it is capable of handling graphs in which some of the edge weights are negative numbers. Negative edge weights are found in various applications of graphs, hence the usefulness of this algorithm. If a graph contains a "negative cycle" (i.e. a cycle whose edges sum to a negative value) that is reachable from the source, then there is no cheapest path: any path that has a point on the negative cycle can be made cheaper by one more walk around the negative cycle. In such a case, the Bellman-Ford algorithm can detect negative cycles and report their existence

**Implementation Algorithm:**

1. send my routing table to all my neighbors whenever my link table changes
2. when I get a routing table from a neighbor on port P with link metric M:
  - a. add L to each of the neighbor's metrics

- b. for each entry (D, P', M') in the updated neighbor's table:
  - i. if I do not have an entry for D, add (D, P, M') to my routing table
  - ii. if I have an entry for D with metric M'', add (D, P, M') to my routing table if  $M' < M''$
3. if my routing table has changed, send all the new entries to all my neighbors.

**Source Code:**

```

import java.util.Scanner;
public class BellmanFord
{

```

```
$ns at 16 "finish"
$ns run
```

**AWK file:** (Open a new editor using “gedit command” and write awk file and save with “.awk” extension)

**cwnd:- means congestion window**

```
BEGIN {
```

```

}
{
if($6= "cwnd_")           # don't leave space after writing cwnd_
printf("%f\t%f\t\n",$1,$7);   # you must put \n in printf
}
END {
}

```

### Steps for execution:

- Open gedit editor and type program. Program name should have the extension “.tcl ”

```
[root@localhost ~]# gedit lab3.tcl
```

- Save the program and close the file.
- Open gedit editor and type **awk** program. Program name should have the extension “.awk ”

```
[root@localhost ~]# gedit lab3.awk
```

- Save the program and close the file.
- Run the simulation program

```
[root@localhost~]# ns lab3.tcl
```

- Here “**ns**” indicates network simulator. We get the topology shown in the snapshot.
- Now press the play button in the simulation window and the simulation will begins.
- After simulation is completed run **awk file** to see the output ,

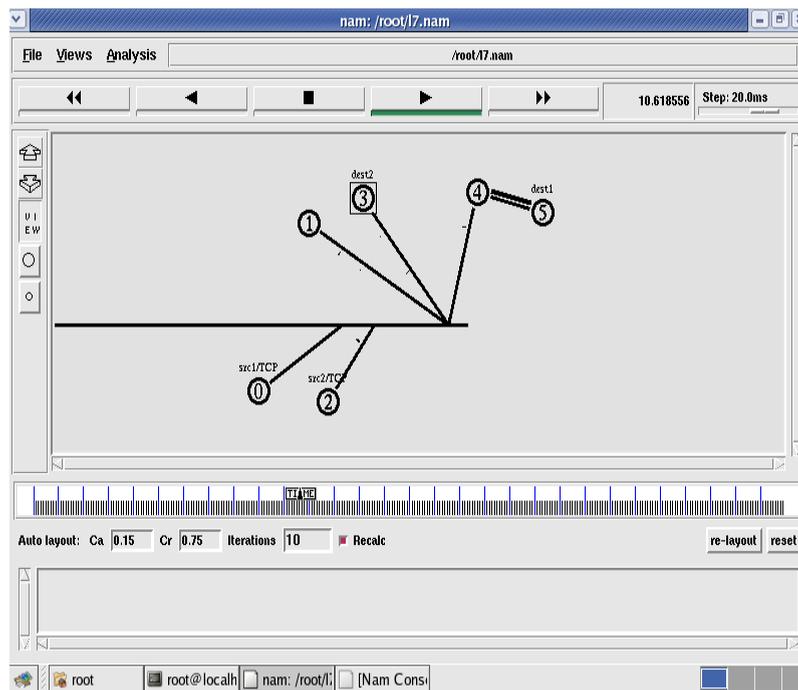

```
[root@localhost~]# awk -f lab3.awk file1.tr > a1
```

```
[root@localhost~]# awk -f lab3.awk file2.tr > a2
```

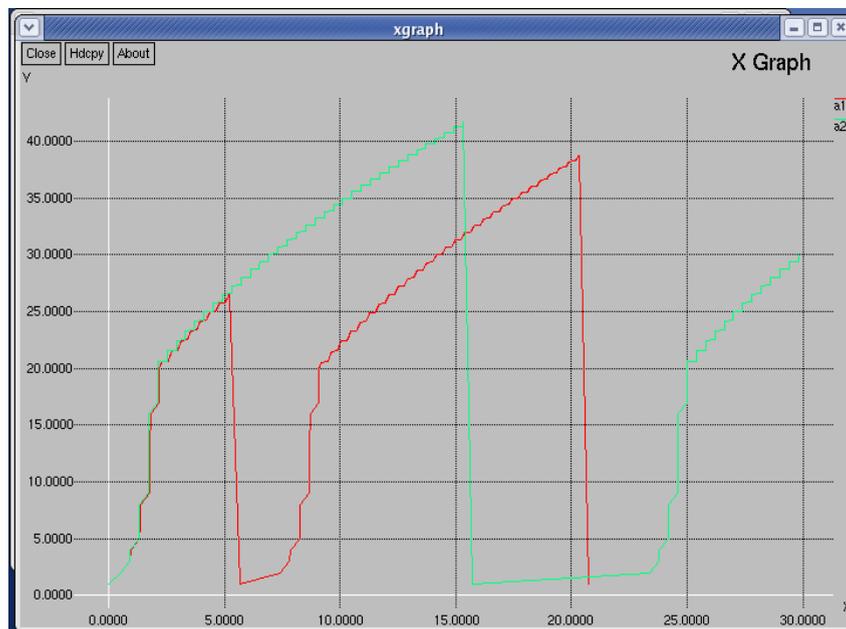

```
[root@localhost~]# xgraph a1 a2\
```

- Here we are using the congestion window trace files i.e. **file1.tr** and **file2.tr** and we are redirecting the contents of those files to new files say **a1** and **a2** using **output redirection operator (>)**.
- To see the trace file contents open the file as ,

### **Topolgy:**

**Output:**

**Experiment No: 7****Date:****CONGESTION CONTROL USING LEAKY BUCKET ALGORITHM****Aim:** *C Program for Congestion control using Leaky Bucket Algorithm*

The main concept of the leaky bucket algorithm is that the output data flow remains constant despite the variant input traffic, such as the water flow in a bucket with a small hole at the bottom. In case the bucket contains water (or packets) then the output flow follows a constant rate, while if the bucket is full any additional load will be lost because of spillover. In a similar way if the bucket is empty the output will be zero.

From network perspective, leaky bucket consists of a finite queue (bucket) where all the incoming packets are stored in case there is space in the queue, otherwise the packets are discarded. In order to regulate the output flow, leaky bucket transmits one packet from the queue in a fixed time (e.g. at every clock tick). In the following figure we can notice the main rationale of leaky bucket algorithm, for both the two approaches (e.g. leaky bucket with water (a) and with packets (b)).

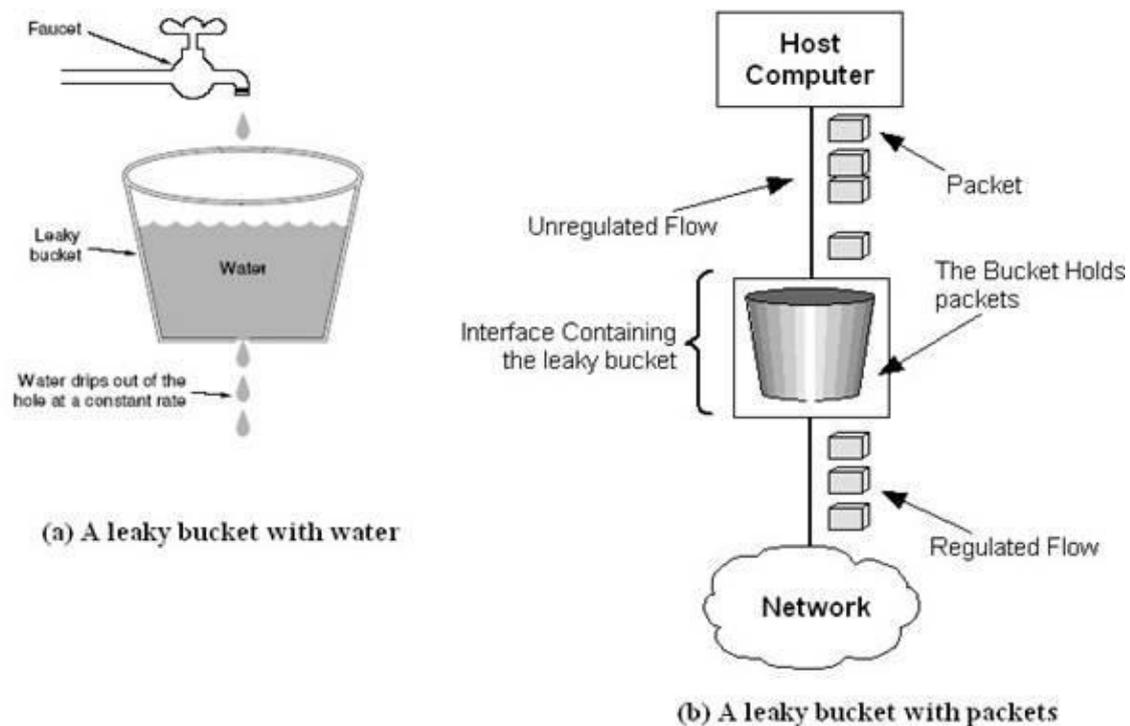

Figure 2.4 - The leaky bucket traffic shaping algorithm

While leaky bucket eliminates completely burst traffic by regulating the incoming data flow its main drawback is that it drops packets if the bucket is full. Also, it doesn't take into account the idle process of the sender which means that if the host doesn't transmit data for some time the bucket becomes empty without permitting the transmission of any packet.

### Implementation Algorithm:

Steps:

1. Read The Data For Packets
2. Read The Queue Size
3. Divide the Data into Packets
4. Assign the random Propagation delays for each packets to input into the bucket (input\_packet).
5. while((Clock++<5\*total\_packets)and  
 (out\_packets< total\_packets))
  - a. if (clock == input\_packet)
    - i. insert into Queue
  - b. if (clock % 5 == 0 )
    - i. Remove packet from Queue

## 6. End

**Source Code:**

```

import java.util.*;
public class leaky
{
    static int min(int x,int y)
    {
        if(x<y)

            drop=0;
            System.out.println();
        }
    }
}

```

```
    }
    for(;count!=0;i++)
    {
    if(count>cap)
    {
    drop=count-cap;
    count=cap;
    }
    System.out.print(i+1);
    System.out.print("\t\t0");
    mini=min(count,process);
    System.out.print("\t\t"+mini);
    count=count-mini;
    System.out.print("\t\t"+count);
    System.out.print("\t\t"+drop);
    System.out.println();
    }
}
```

**Output:**

Enter The Bucket Size

5

Enter The Operation Rate

2

Enter The No. Of Seconds You Want To Stimulate

3

Enter The Size Of The Packet Entering At 1 sec

5

Enter The Size Of The Packet Entering At 1 sec

4

Enter The Size Of The Packet Entering At 1 sec

3

Second|Packet Recieved|Packet Sent|Packet Left|Packet Dropped|

-----  
1            5            2            3            0

2	4	2	3	2
3	3	2	3	1
4	0	2	1	0
5	0	1	0	0

**VIVA-QUESTIONS:**

1. What are functions of different layers?
2. Differentiate between TCP/IP Layers and OSI Layers
3. Why header is required?
4. What is the use of adding header and trailer to frames?
5. What is encapsulation?
6. Why fragmentation requires?
7. What is MTU?
8. Which layer imposes MTU?
9. Differentiate between flow control and congestion control.
10. Differentiate between Point-to-Point Connection and End-to-End connections.

11. What are protocols running in different layers?
12. What is Protocol Stack?
13. Differentiate between TCP and UDP.
14. Differentiate between Connectionless and connection oriented connection.
15. Why frame sorting is required?
16. What is meant by subnet?
17. What is meant by Gateway?
18. What is an IP address?
19. What is MAC address?
20. Why IP address is required when we have MAC address?
21. What is meant by port?
22. What are ephemeral port number and well known port numbers?
23. What is a socket?
24. What are the parameters of socket()?
25. Describe bind(), listen(), accept(),connect(), send() and recv().
26. What are system calls? Mention few of them.
27. What is IPC? Name three techniques.
28. Explain mkfifo(), open(), close() with parameters.
29. What is meant by file descriptor?
30. What is meant by traffic shaping?
31. How do you classify congestion control algorithms?
32. Differentiate between Leaky bucket and Token bucket.
33. How do you implement Leaky bucket?
34. How do you generate busty traffic?
35. What is the polynomial used in CRC-CCITT?
36. What are the other error detection algorithms?
37. What is difference between CRC and Hamming code?
38. Why Hamming code is called 7,4 code?
39. What is odd parity and even parity?
40. What is meant by syndrome?
41. What is generator matrix?
42. What is spanning tree?
43. Differentiate between Prim's and Kruskal's algorithm.

44. What are Routing algorithms?
45. How do you classify routing algorithms? Give examples for each.
46. What are drawbacks in distance vector algorithm?
47. How routers update distances to each of its neighbor?
48. How do you overcome count to infinity problem?
49. What is cryptography?
50. How do you classify cryptographic algorithms?
51. What is public key?
52. What is private key?
53. What are key, ciphertext and plaintext?
54. What is simulation?
55. What are advantages of simulation?
56. Differentiate between Simulation and Emulation.
57. What is meant by router?
58. What is meant by bridge?
59. What is meant by switch?
60. What is meant by hub?
61. Differentiate between route, bridge, switch and hub.
62. What is ping and telnet?
63. What is FTP?
64. What is BER?
65. What is meant by congestion window?
66. What is BSS?
67. What is incoming throughput and outgoing throughput?
68. What is collision?
69. How do you generate multiple traffics across different sender-receiver pairs?
70. How do you setup Ethernet LAN?
71. What is meant by mobile host?
72. What is meant by NCTUns?
73. What are dispatcher, coordinator and nctunsclient?
74. Name few other Network simulators
75. Differentiate between logical and physical address.
76. Which address gets affected if a system moves from one place to another place?

77. What is ICMP? What are uses of ICMP? Name few.

78. Which layer implements security for data?
