## Exam 2 Review CS 1134, Spring 2026

**Disclaimer:** This mock exam is only for practice. It was made by tutors in the Polytechnic Tutoring Center and is not representative of the actual exam given by the CS Department.

### Question 1 A (5 points)

Translate the following prefix expressions into postfix, and find its value:

“- \* 3 + 2 4 / 5 + 6 1”

Value = \_\_\_\_\_

Postfix expression = \_\_\_\_\_

### Question 1 B (1 points each, total 8 points)

```
class ArrayQueue:
```

```
    INITIAL_CAPACITY = 2
```

```
    def __init__(self):
```

```
        self.data_arr = make_array(ArrayQueue.INITIAL_CAPACITY)
```

```
        self.capacity = ArrayQueue.INITIAL_CAPACITY
```

```
        self.n = 0
```

```
        self.front_ind = None
```

```
    def __len__(self): ...
```

```
    def is_empty(self): ...
```

```
    def enqueue(self, elem): ...
```

```
    def dequeue(self): ...
```

```
    def first(self): ...
```

```
    def resize(self, new_cap): ...
```

Consider the ArrayQueue class on page 1. Fill in the table after each operation:

| Operator                | Return value | front_ind | n | capactiy | data_arr |
|-------------------------|--------------|-----------|---|----------|----------|
| <b>q = ArrayQueue()</b> |              |           |   |          |          |
| <b>q.enqueue('A')</b>   |              |           |   |          |          |
| <b>q.enqueue('B')</b>   |              |           |   |          |          |
| <b>q.first()</b>        |              |           |   |          |          |
| <b>q.dequeue()</b>      |              |           |   |          |          |
| <b>q.enqueue('C')</b>   |              |           |   |          |          |
| <b>q.enqueue('D')</b>   |              |           |   |          |          |
| <b>q.first()</b>        |              |           |   |          |          |

**Question 2 (3 points each, total 12 points)**

From the following binary tree, write down the different traversals inside of the table on the next page

| Traversal            | Your Answer |
|----------------------|-------------|
| Preorder             |             |
| Inorder              |             |
| Postorder            |             |
| Breadth First Search |             |

### Question 3 (20 points)

We define a new data structure called **ReversibleQueue**, which behaves like the `ArrayQueue` studied in class, but additionally supports a `reverse()` operation. Implement the operations on the next page using the requirements below.

#### Implementation Requirements:

A `ReversibleQueue` has the following operations:

1. `rq = ReversibleQueue()`: creates a new empty `ReversibleQueue` object.
2. `rq.is_empty()`: returns `True` if there are no elements in `rq`, or `False` otherwise.
3. `len(rq)`: returns the number of elements currently stored in `rq`.
4. `rq.enqueue(elem)`: inserts `elem` into `rq`.
5. `rq.dequeue()`: removes and returns the element that is currently first in line in `rq`, or raises an `Exception` if `rq` is empty.
6. `rq.first()`: returns (without removing) the element that is currently first in line in `rq`, or raises an `Exception` if `rq` is empty.
7. `rq.reverse()`: mutates `rq` so that the order of its elements is reversed.

**For example, these operations should work:**

```
>>> rq = ReversibleQueue()
>>> rq.enqueue(10)
>>> rq.enqueue(20)
>>> rq.enqueue(30)
>>> rq.first()
10
>>> rq.reverse()
>>> rq.first()
30
>>> rq.dequeue()
30
>>> rq.dequeue()
20
>>> rq.dequeue()
10
```

```
class ReversibleQueue:
```

```
    def __init__(self):
```

```
        def __len__(self):
```

```
        def is_empty(self):
```

```
        def enqueue(self, elem):
```

```
        def dequeue(self):
```

```
def first(self):
```

```
def reverse(self):
```

#### Question 4 (15 points)

Add a method to the DoublyLinkedList class:

```
def move_to_front(self, node_to_move)
```

when called on a non-empty DoublyLinkedList object, the method should **mutate** the list in-place to move a node and make it the topmost node of the list. The `node_to_move` is passed in as a reference to any node in any part of the list. For example, given a list that looks like this:

[1-2-3-4-5]

and given a reference to the node containing data 4, we should get:

[4-1-2-3-5]

you can assume `node_to_move` will never be a reference to the header or trailer node.

*The method must have a linear runtime, or better*

**Answer is re-implementation of `delet_node` and `add_first`.**

### Question 5 (15 points)

Implement the following function which takes in a queue and a non negative integer k.

`def reverse_first_k(q, k):`

When called, it should reverse the first k elements of the queue. The remaining elements must stay in the same relative order.

If the q initially contains: <1, 2, 3, 4, 5>

After calling: `reverse_first_k(q, 3)`

Q will be: <3, 2, 1, 4, 5>

#### Requirements

You may use one ArrayStack and the function should run in  $O(n)$  time.

### Question 6 (10 points)

Consider the following definition of the **left circular shift** operation:

If  $q$  is a queue containing the sequence

$\langle a_1, a_2, \dots, a_{n-1}, a_n \rangle$

the **left circular shift** of  $q$  is:

$\langle a_2, a_3, \dots, a_n, a_1 \rangle$

That is, the sequence obtained by moving the **front element to the back**, while shifting all other elements forward.

For example:

If variable  $q$  contains =  $\langle 2, 4, 6, 8, 10 \rangle$

After calling after calling `left_circular_shift(q)`,  
 $q$  contains =  $\langle 4, 6, 8, 10, 2 \rangle$

```
def left_circular_shift(q):
```
