

# What is Meiosis?

A division of the  
nucleus that  
reduces  
chromosome

number by half.

- Important in

sexual

reproduction

- Involves

combining the

genetic  
information of  
one parent with  
that of the the  
other parent to  
produce a

genetically

distinct

individual

- ***Diploid*** - two

sets of

chromosomes

(2n), in

humans 23

pairs or 46 total

- ***Haploid*** -

one set of

chromosomes

(n) - gametes

or

sex cells, in

humans 23

chromosomes

# *Homologous pair*

– each

chromosome in  
pair are

identical to the

other ( carry  
genes

for same trait)

– only one pair  
differs - sex

chromosomes X

or Y

Phases of

Meiosis

- A diploid

cell replicates

its

chromosomes

- Two stages  
of meiosis

- Cells divide  
twice but only  
replicate their  
DNA once

***Synapsis*** -

pairing of  
homologous  
chromosomes forming a  
***tetrad.***

- ***Crossing***

***over*** -

**chromatids**

**of tetrad**

**exchange**

parts.

# Prophase I

- Chromosomes condense

Homologous

chromosomes pair

w/

each other

- Each pair contains four sister

chromatids - tetrad

- Crossing over occurs

poks/Cole-Thomson Learning

homologous chromosome

pair

As the chromosomes

move closer together, synapsis

occurs.

Chromatids break,

and genetic information is

exchanged.

•

# Metaphase

I

Tetrads or

homologous

chromosomes

move to

center of cell

2003 Brooks/Cole -

Thomson Learning

**Metaphase I**

**The homologous chromosomes line up in the center of the cell and are still held together**

# Anaphase

Homologous  
chromosomes  
pulled to  
opposite poles

©2003 Brooks/Cole -  
on Learning

# Anaphase I

.

Spindle fibers shorten

- The homologous chromosomes are separated (the sister chromatids are still paired)

***Independent***

***assortment*** - random

chromosomes move to

each pole; some may be

maternal and some may  
be paternal

# Telophase I

Daughter

nuclei formed

.

These are

haploid ( $1n$ )

roaug root@

Thomson Learning

88

**Telophase I**

- The nuclear membrane reforms **around** each

daughter nucleus

- Each new cell now contains **two** sister

chromatids that are NOT identical **due** to

**crossing** over

[b]

# At the end of Meiosis I...

- You have made **2 cells**

- Each cell contains a haploid number of chromosomes - **1 copy** of each chromosome

(**for** humans, each haploid cell has 23 chromosomes)

## Meiosis II

Daughter cells

undergo a

second division;

much like

mitosis

***NO ADDITIONAL  
REPLICATION  
OCCURS***

•  
**Spindle**

# Prophase II

fibers form

again

S

- # Prophase I

Nuclear membrane  
breaks down again

## Metaphase II

•  
Sister

chromatids

move to the

center

**Metaphase II**

The chromosomes line  
**up** in the middle of the  
cell.

Telophase II &

# Cytokinesis

Four haploid

daughter cells

results from

one original diploid

cell

# Telophase II

Nuclear envelope  
re-forms around the  
four  
sets of daughter

chromosomes.

Four haploid daughter cells

5842

.

**At the end of**

**Meiosis II...**

At the end of  
Meiosis II, there are  
4 haploid cells.

(only 1 copy of  
each

chromosome)

- (for humans, each

haploid cell has 23  
chromosomes

**No** two of these  
haploid cells are  
alike due to  
crossing over.

This is why you and  
your siblings are  
genetically unique!

## **Review Mitosis & Meiosis**

**Both are forms of  
nuclear division**

Both involve  
replication

Both involve  
disappearance  
of the nucleus,  
and nucleolus,  
nuclear membrane

.

Both involve  
formation of  
spindle

fibers

***DIFFERENCES***

***Meiosis***

produces  
daughter cells  
that have  $1/2$  the  
number of  
chromosomes as  
the parent. Go  
from  $2n$  to  $1n$ .

**Daughter *cells***  
produced by  
meiosis are **not**  
genetically  
**identical** to one  
another.

- In ***meiosis*** cell

division takes  
place **twice** but  
replication occurs  
**only once.**
