Hello, World!

1. Create and run a "Hello, World!" project in Eclipse:
 - a. Start Eclipse
 - b. Choose a workspace (e.g. S:\CP2\workspace)
 - c. Go to the workbench
 - d. Create a new Java project **HelloWorldApp**
 - e. Create a new class **HelloWorldApp**:

```
/**
 * The HelloWorldApp class implements an application that
 * simply prints "Hello World!" to standard output.
 */
class HelloWorldApp {
    public static void main(String[] args) {
        System.out.println("Hello World!"); // Display the string.
    }
}
```

Java Basics

- Syntax vs. Python / C++
 - Java syntax is very similar to C++
 - Wikipedia: [Comparison of Java and C++](#)
- Java is object-oriented from the ground up, even your "Hello, World!" program needs to implement a class!
- Java class terminology:
 - Class data members are called **fields**.
 - Class functions are called **methods**.
- In Java, every application must contain a main method with this **signature (header)**:

```
○ public static void main(String[] args)
```

Example class

Person class template

- This is a template only - notice that the methods are not implemented.
- create a new class Person, or new file Person.java and copy the code below

```
public class Person {

    /******* Fields - default access level *****/

    String _fName;    // first name
    String _lName;    // last name
    String _DOB;      // date of birth in "MM-DD-YYYY" format

    /******* Constructors *****/

    // initialize fields to default values
    public Person(){ }

    // initialize fields using parameters
    public Person(String f, String l){ }

    // initialize fields using parameters
    public Person(String f, String l, String dob){}

    /******* Overrides *****/

    // return a String that represents this object
    public String toString(){ return "not implemented"; }

    /******* Private method(s) *****/

    // return true if dob is in valid "MM-DD-YYYY" format, else false
    private boolean validDOB( String dob ){ return true; }

    /******* Getters and setters *****/

    // return value of _name
    public String getName(){ return "not implemented"; }

    // change value of _name
    public void setName(String first, String last){ }

    /******* Main *****/

    // construct Person objects and test methods
    public static void main(String[] args){
        Person p1 = new Person();
        System.out.println( p1 );

        p1.setName( "new", "name" );
        // etc...
    }
}
```

Examining the Person class

- **Constructors**
 - The **default constructor** is the no-parameter constructor - `Person()`
 - **Overloading** is the process of creating multiple methods with the same name but different parameters.
 - This allows you to use a method in different ways - see the 3 versions of the `Person` object constructor below.
- **toString**
 - **toString** is a method of `Object` that returns a `String` representing the object.
 - `toString` is called implicitly (automatically) when you print an object using `System.out.println`.
 - You should define `toString` in (just about) every class you create.
- [Access modifiers](#)
 - From least to most restrictive: { `public`, `protected`, (default), `private` }
 - Right now we'll just use default (no modifier) or `public`.
 - **default** - any class in the same package can access.
 - **public** - any class in the same project can access.
- **Getters and setters**
 - In many situations, another class without access to a field will need to get or set the field's values. To support this, you implement methods to **get / set**.
 - It's good practice to use getters and setters, so that you can change the underlying **implementation** of a class without changing the **interface**.
- **main**
 - `main` is a **static method**
 - **static methods (or fields)** are a.k.a. class methods - they exist independently of any created objects
 - It's best for now to just think of `main` in C++ terms - as if it is a separate entity from your class.
