API Documentation

<https://apiuat.transerve.com/api-docs/#/>

After rounds of discussion where the APIs and their use cases were explained to me, I was in charge of their documentation. Please note that the link I have provided might have been updated after I left but for reference, I was responsible for the documentation contained in the *Layers* and *Forms* sections.

Tools Usage Manuals

Spatial Interpolate Tool

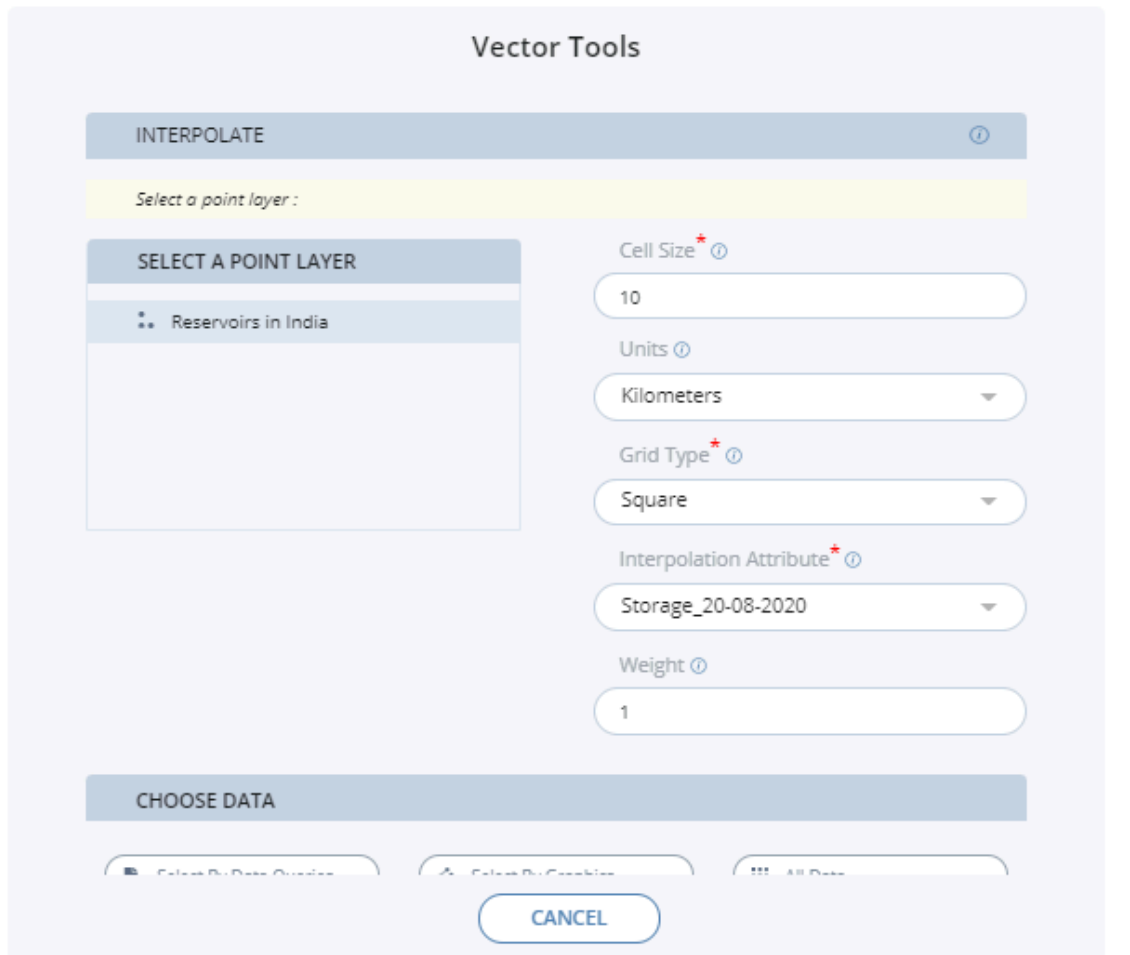

Vector Processing Tools

Spatial Analysis - Interpolate

This feature requires at least one point in the layer to be implemented. It makes use of the Inverse Distance Weighing method to interpolate points in a grid pattern based on the parameters provided by the user. The Inverse Distance Weighing method is implemented to determine the values at unknown points using the weighted average of the known points. This process is known as interpolation.

The interpolate option can be selected by going to
Tools -> Vector Processing Tools -> Spatial Analysis -> Interpolate

Once the interpolate option is selected, a window is displayed where the user gets to select the data layers and the deciding factors for the interpolation.

1. Cell Size - Calculates the input size of every cell.
2. Units - Determines the measurement of the cell size
3. Grid Type - Determines the grid geometry between a square, point, triangle and hexagonal cell.
4. Interpolation Attribute - A numeric attribute to be used as the interpolation parameter. This option is enabled only if the dataset contains a numeric attribute to be used as the interpolation attribute.
5. Weight - With a default value of 1, this parameter determines the impact of the input values.

Select By Data Queries

This option redirects the user to the Query Builder. The interpolate operation is carried out on the output of the query created. More information about the query builder and how to create custom queries can be found here.

Output for square grid type -

Select By Graphics

This option gives the user the choice to manually select the region around which the operation should be applied. There are three ways of selection.

1. Point Selection

The interpolate operation does not produce an output for a single point selection.

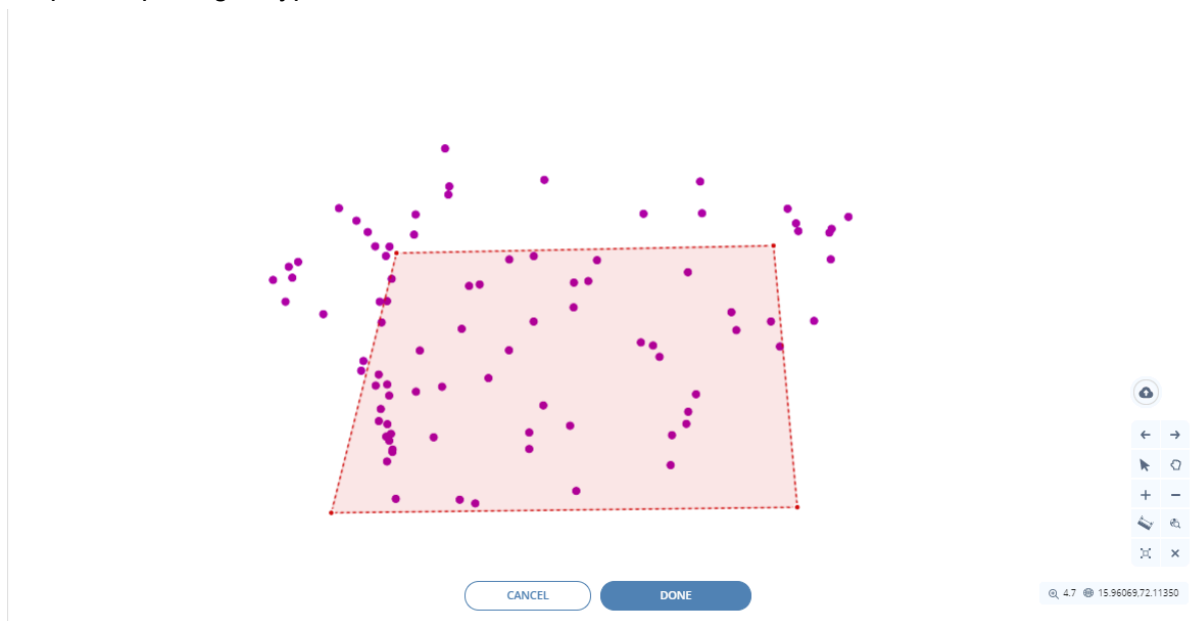

2. Polyline Selection

The interpolate operation does not produce an output for polyline selection as the selection of multiple points without enclosing a region is considered as invalid geometry.

3. Polygon Selection

This tool produces the overlapping region between the enclosed area selected by the user and the other polygon layers.

Output for point grid type -

4.6 @ 15.96069,72.11350

All Data

Implements the interpolate operation on the entire map session layers selected by the user.

Output for hex grid type -

The output polygon represents the intersection using a highlighted region. A table including the area is also produced. The user has the option to save the data permanently by creating a new session map with the output layer. Similarly, the option to save the data temporarily uses the output to create a new layer within the same map session.

Spatial Filter Tool

Raster Processing Tools

Analysis - Spatial Filter

This tool implements spatial filtering on a line string elevation dataset using a specific slope range as a filtering condition.

The Spatial Filter can be selected by going to
Tools -> Raster Processing Tools -> Analysis -> Spatial Filter

This option redirects the user to a window where they can select the layers and fill in the values for the parameters required for this operation. This tool requires both a raster and a line string layer for its execution.

Raster Tools : Analysis

SPATIAL FILTER

Select raster

tile-5-4

Select a linestring layer to filter

tile-5-4-gradual-path

Select slope range ⓘ

Minimum slope

30

Maximum slope

70

Enter buffer radius (meters)

100

CANCEL FILTER

1. Slope Range - Determines the minimum and maximum elevation value between which the layer should be filtered.

2. Buffer Radius - The spatial filter is applied to the area of the buffer radius for every point in the line string.

Once the values are finalized, the 'Filter' option can be selected to produce an output layer containing the filtered raster file. This layer is added to the user's data library and map session as soon as it's processed.

Spatial Intersection Tool

Vector Processing Tools

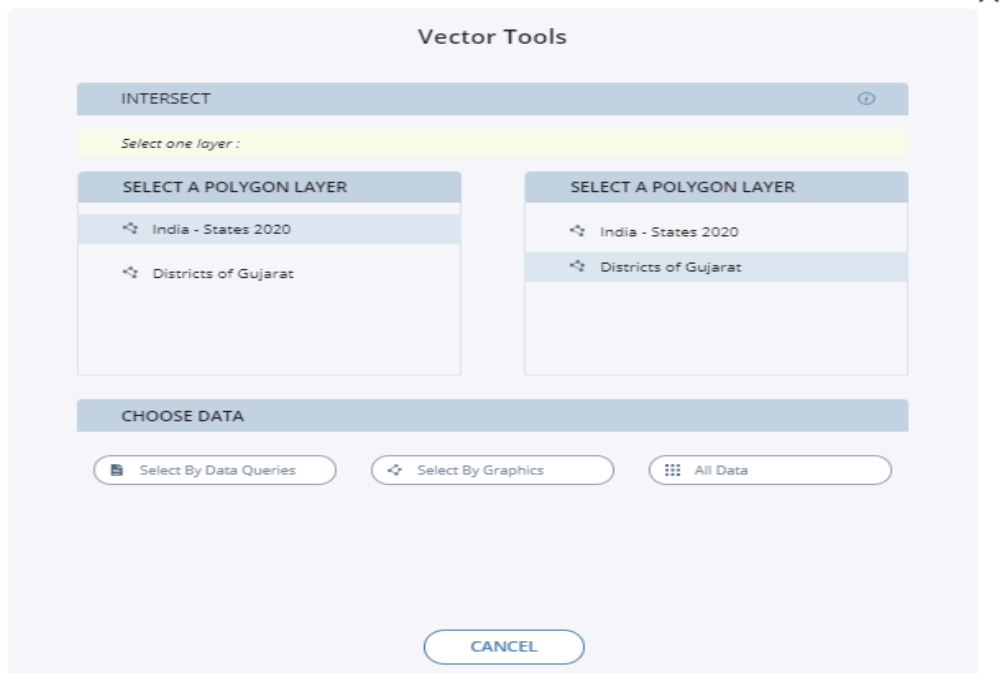

Spatial Analysis - Intersection

This tool makes use of two layers from which the output produced gives the overlapping region between the two layers.

The intersection option can be selected by going to
Tools -> Vector Processing Tools -> Spatial Analysis -> Intersect

The selection of the intersect option displays a window where the user gets to select the two layers required for the operation. Once the data is selected, the option to determine the range of data is produced.

Select By Data Queries

This option redirects the user to the Query Builder. The Bounding Box operation is carried out on the output of the query created. More information about the query builder and how to create custom queries can be found [here](#).

Nodata Found

Select By Graphics

This option gives the user the choice to manually select the region around which the operation should be applied. There are three ways of selection.

1. Point Selection

The intersection operation includes the overlap of the region surrounding the point and the other polygon layers.

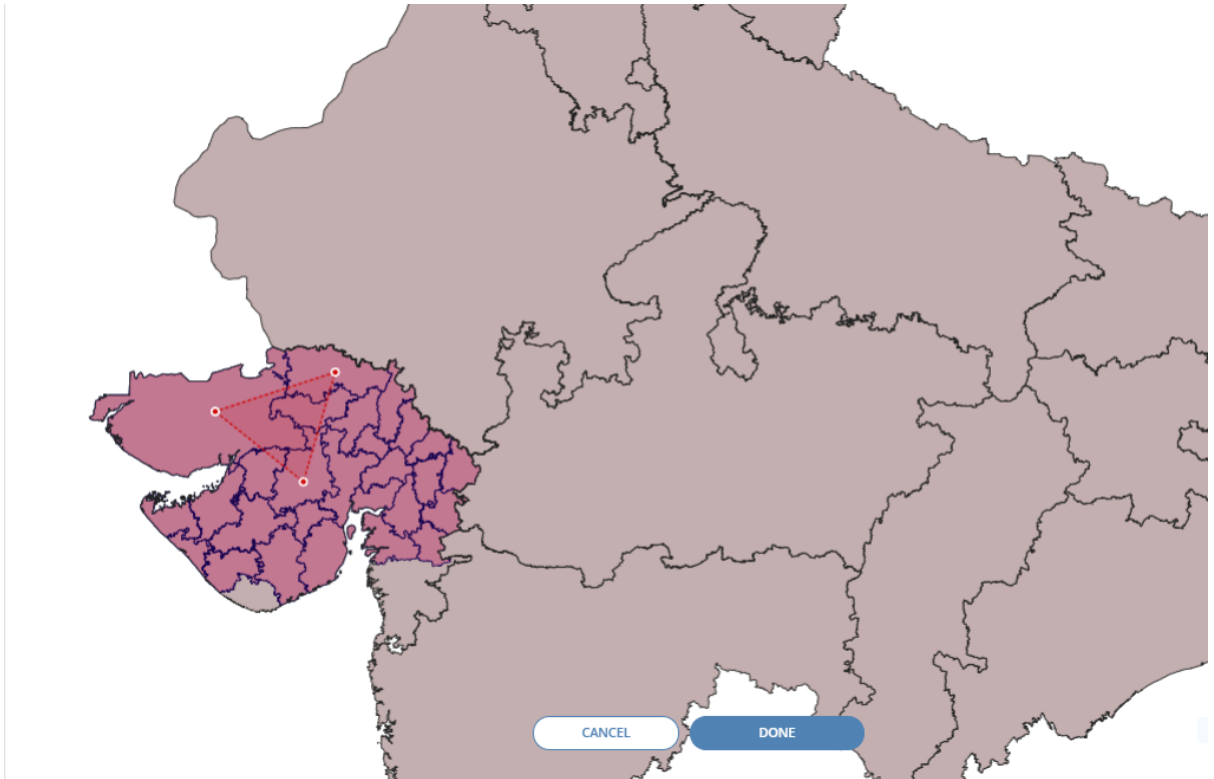

2. Polyline Selection

The intersection operation does not produce an output for polyline selection as the selection of multiple points without enclosing a region is considered as invalid geometry.

3. Polygon Selection

This tool produces the overlapping region between the enclosed area selected by the user and the other polygon layers.
