The Curious Case of the Curious Case: Detecting Touchscreen Events Using a Smartphone Protective Case.

Abstract:
Security-conscious users are very careful with software they allow their phone to run. They are much less careful with the choices they make regarding accessories such as headphones or chargers and only few, if any, care about cyber security threats coming from the phone's protective case. We show how a malicious smartphone protective case can be used to detect and monitor the victim's interaction with the phone's touchscreen, opening the door to keylogger-like attacks, threatening the user's security and privacy. This feat is achieved by implementing a hidden capacitive sensing mechanism inside the case. Our attack is both sensitive enough to track the user's finger location across the screen, and simple and cheap enough to be mass-produced and deployed en masse. We discuss the theoretical principles behind this attack, present a preliminary proof-of-concept, and discuss potential countermeasures and mitigations.

Design and Control of Small Mobile Phone Automatic Film Pasting Machine

Abstract:
Aiming at the following problems, low efficiency of manual film, easy to produce bubbles and irregular, the small semi-automatic pasting machine is inconvenient, the large automatic pasting machine is expensive, a new automatic film pasting machine for mobile phone is put forward. The automatic film pasting machine is mainly composed of clamping, driving, cleaning, positioning and foil, it can remove implementation the functions of mobile phone screen cleaning, remove protective layer, automatically align the mobile phone screen and film. The power system is driven by a stepping motor, and the automatic control of the stepping motor is realized by AT89C51 single chip. The driving circuit of the stepping motor is composed of ULN2003. The display screen selects 8*8 LED display screen, and gives the display control circuit based on 51 single chip microcomputer. The result shows that the automatic film pasting machine achieves the preset functional requirements, the structure is simple, and the film holding efficiency is improved.

Micromachining of gorilla glass

Abstract:
For the first time, this paper presents micromachining of gorilla glass, which is a new tough and transparent substrate, but has not been used in MEMS yet. We have demonstrated that microstructures made of Gorilla glass have several advantages for MEMS applications, including flexibility and high fracture toughness. Wet etching with hydrofluoric acid (HF) was found more effective because it prevents creation of sharp corners. The process was optimized with an additive of hydrochloric acid (HCl) to reduce surface roughness, and the etching rate is approximately 12 μm/min. The microcantilevers made of Gorilla glass is capable to bend 12.26 degrees without breaking, which is very different from the conventional brittle glass (including Pyrex or Borosilicate).

ABSTRACT

Thermoluminescence and phototransferred thermoluminescence measurements of protective glass from smartphones are described. Samples of Gorilla Glass were examined from nine different manufacturers and 40 different phone models. Additionally, 12 glasses believed to be original equipment manufacturer replacements, as well as three glass samples from U.S. finishers, were also studied. Altogether, 99 different Gorilla Glass samples were examined. The radiation-induced thermoluminescence signal produced glow curve shapes specific to the Gorilla Glass generations and could be used to distinguish between them. A background thermoluminescence (and phototransferred thermoluminescence) signal was found in all unirradiated samples. Its intensity and shape were found to be dependent on the Gorilla Glass generation, phone manufacturer, and phone model. The background signal was demonstrated to be produced by ultraviolet light exposure; the shape of the background signal was able to be reproduced by the combined exposure to a broad-spectrum solar simulator and a 302 nm ultraviolet light source. The background signal intensity was found to vary with the location from which it was taken on the glass. It was also found to be dependent on the depth within the Gorilla Glass due to absorption of the ultraviolet light as it traversed the medium. Removal of the glasses' surface layers was found to be an inadequate method for removing the background signal. In some samples, the background signal intensity was large enough to significantly contribute to the total thermoluminescence (and phototransferred thermoluminescence) signal; therefore, a matrix deconvolution method was introduced to separate the background signal and radiation-induced signal. This method was found to enable dose reconstruction using the radiation-induced signal alone.

Journal of Physics: Conference Series, Volume 1616, 3rd International Symposium on Big Data and Applied Statistics 10-12 July 2020, Kunming, China

Citation Hailang Chen 2020 *J. Phys.: Conf. Ser.* **1616** 012101

Abstract

With the advancement of the intelligent era of Industry 4.0, in order to solve the problem of low-efficiency and high miss-detection rate using manual visual inspection for the detection of surface defects on smartphone protective screens, surface defects on smartphone protective screens based on convolutional neural networks are introduced as the detection method. This detection method exhibits excellent feature extraction capabilities and powerful target classification performance during the preprocessing, model design, model training, and detection of smartphone protective screens images. Experimental results show that the detection method can achieve accurate detection of defects such as punctures, bright spots, and scratches on the surface of the smartphone protective screens. The detection verification rate is as high as 98%, and the accuracy is high, which meets the actual needs of enterprises.
