

## Identifying and Analyzing Network/Host Intrusion Detection System Alerts

The purpose of this lab is to introduce the concept of network and host monitoring using the Security Onion platform. The lab involves setting up Security Onion on a Kali machine and using Zenmap to perform an intense scan on multiple networks to identify common ports. In the second part of the lab, the command "sudo service nsm status" is used to monitor all networks for RealTime Events, and the packet data is analyzed for potential security incidents. A report is generated, highlighting potential security issues such as ET SCAN NMAP OS Detection. In the third part of the lab, Squert is used to apply filters to analyze traffic from a specific IP address (10.1.1.10) to the DVL Server on eth0 interface, enabling security analysts to identify potential threats and generate visual reports.

### 1. Define IDS, Host-Based IDS and Network-Based IDS:

**IDS** stands for Intrusion Detection System. It is a security technology that monitors network or system activities for malicious activities or policy violations. IDSs are designed to detect and respond to various types of attacks or unauthorized activities in real-time or near real-time.

**Host-Based IDS (HIDS)** is an IDS that focuses on monitoring and analyzing activities on individual hosts or endpoints within a network. It operates by installing software agents or sensors on the host systems to monitor and analyze local event logs, system files, and network connections. HIDS looks for signs of intrusion or suspicious behavior on a specific host, such as unauthorized access attempts, file modifications, or abnormal network traffic patterns. It provides a more detailed view of the host's security status and helps in detecting attacks targeting a specific system.

**Network-Based IDS (NIDS)**, on the other hand, monitors network traffic and analyzes it for signs of malicious activities or policy violations. It operates by capturing and inspecting network packets flowing through network devices, such as routers, switches, or dedicated sensors. NIDS examines packet headers and payloads, looking for patterns or signatures of known attacks or anomalous behavior. It can identify various types of network-based attacks, including network scanning, denial-of-service (DoS) attacks, and intrusion attempts targeting specific services or protocols. NIDS provides a broader view of the network's security posture and helps in detecting attacks targeting multiple hosts or network segments.

### 2. What is Security Onion and what is it used for?

**Security Onion** is a free and open-source platform for network security monitoring and intrusion detection. It is a Linux distribution that integrates several security tools and components into a unified system. Security Onion provides a complete solution for network security monitoring, log management, and analysis.

The primary purpose of Security Onion is to assist in detecting and responding to security incidents within a network. It combines various components and tools to provide comprehensive network security capabilities.

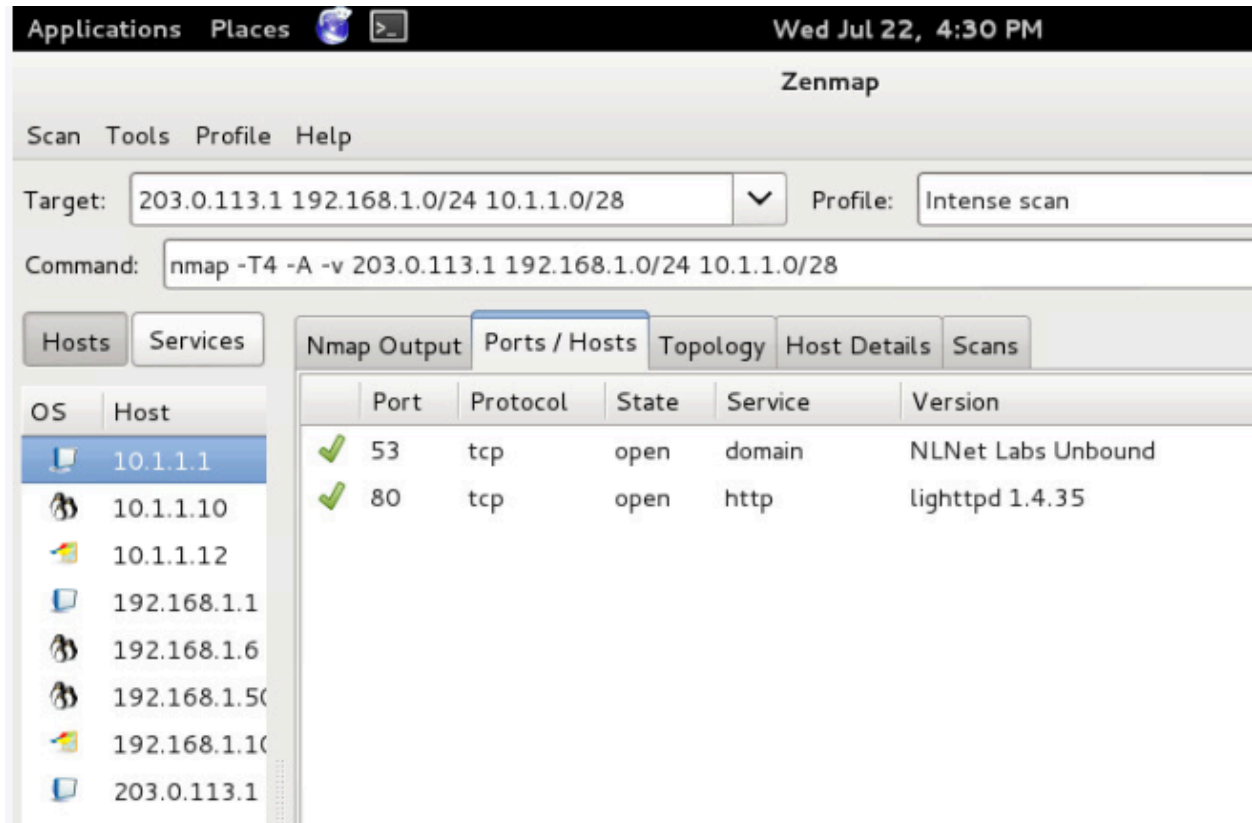

### 3. Define Sguil and Squert and how they relate to one another:

**Sguil and Squert** are two components of the Security Onion platform that work together to provide enhanced network security monitoring and analysis capabilities.

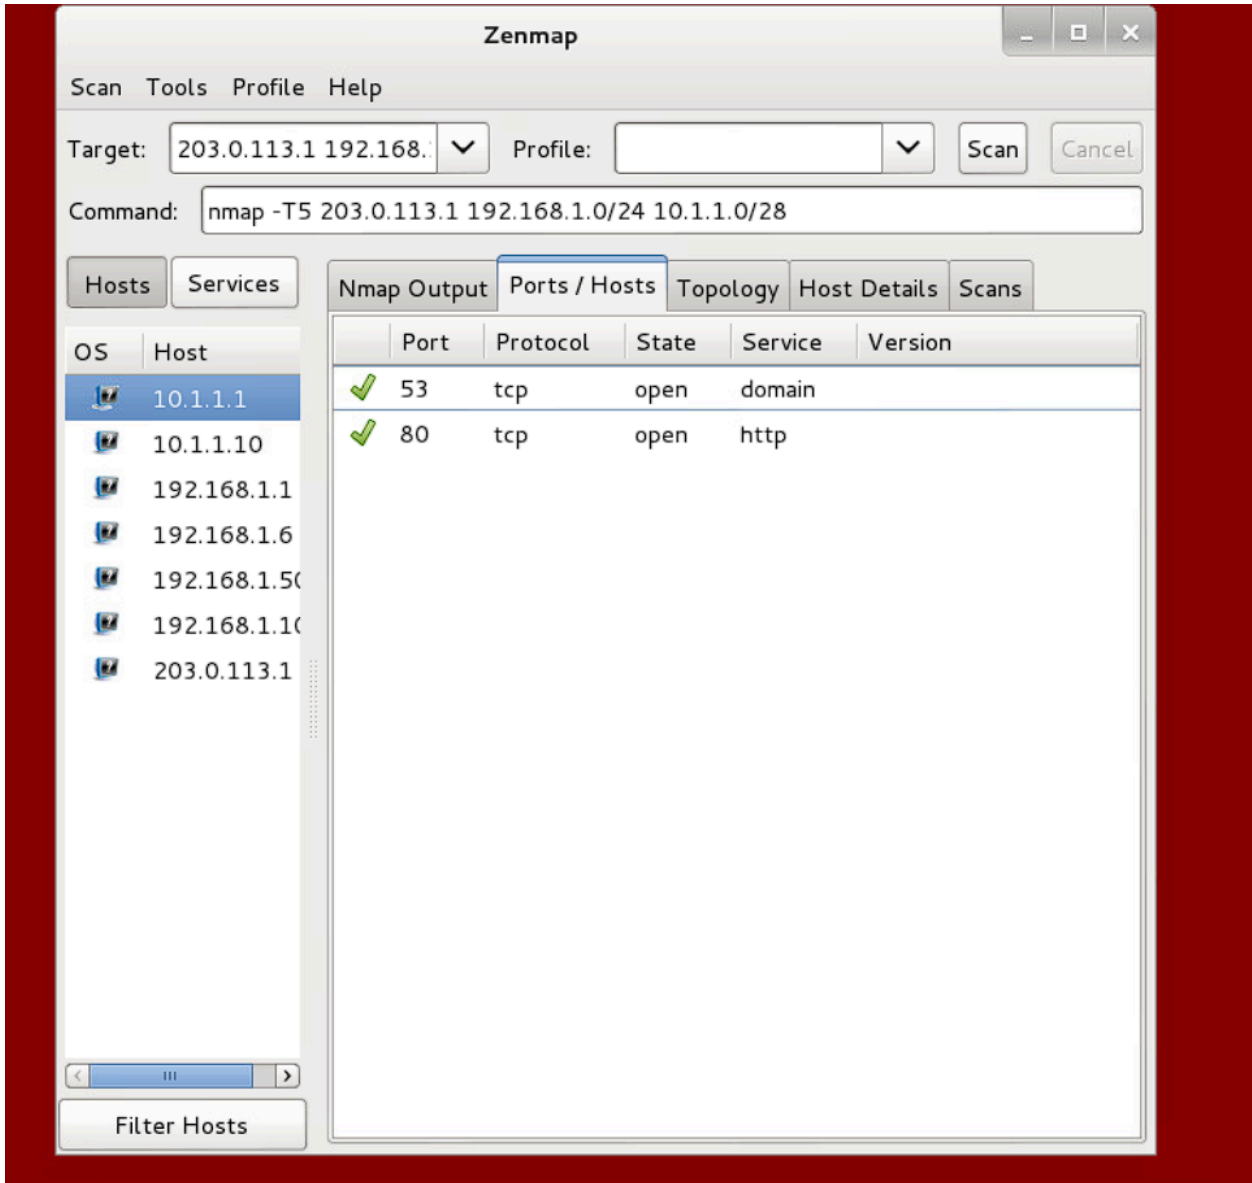

**Sguil** is a graphical user interface (GUI) that serves as a central management console for Security Onion. It integrates various security tools, including intrusion detection systems (IDS), packet capture tools, and log management systems, into a unified interface. Sguil provides a single pane of glass for security analysts to monitor and investigate security events in real-time.

**Sguil and Squert** are complementary components of the Security Onion platform. Sguil serves as the central management console for security monitoring and investigation, while Squert provides a visual representation and analysis of security events. Together, they enhance the capabilities of Security Onion by enabling real-time monitoring, event correlation, investigation, collaboration, and visual analysis for network security incidents.

On page 7, import the snapshot equivalent to Figure 10. Include the list of various hosts that were scanned by Zenmap. See the example below:

4. Import your snapshot (similar to example above) here:

On page 9, import the snapshot equivalent to Figure 5. See the example below:
