

Formative Assessment Exemplar - BIO.4.3

Introduction:

The following formative assessment exemplar was created by a team of Utah educators to be used as a resource in the classroom. It was reviewed for appropriateness by a Bias and Sensitivity/Special Education team and by state science leaders. While no assessment is perfect, it is intended to be used as a formative tool that enables teachers to obtain evidence of student learning, identify gaps in that learning, and adjust instruction for all three dimensions (i.e., Science and Engineering Practices, Crosscutting Concepts, Disciplinary Core Ideas) included in a specific Science and Engineering Education (SEEd) Standard.

In order to fully assess students' understanding of all three dimensions of a SEEd standard, the assessment is written in a format called a cluster. Each cluster starts with a phenomenon, provides a task statement, necessary supporting information, and a sequenced list of questions using the gather, reason, and communicate model (Moulding et al., 2021) as a way to scaffold student sensemaking. The phenomenon used in an assessment exemplar is an analogous phenomenon (one that should not have been taught during instruction) to assess how well students can transfer and apply their learning in a novel situation. The cluster provides an example of the expected rigor of student learning for all three dimensions of a specific standard. In order to serve this purpose, this assessment is NOT INTENDED TO BE USED AS A LESSON FOR STUDENTS.

Because this assessment exemplar is a resource, teachers can choose to use it however they want for formative assessment purposes. It can be adjusted and formatted to fit a teacher's instructional needs. For example, teachers can choose to delete questions, add questions, edit questions, or break the tasks into smaller segments to be given to students over multiple days.

General Format:

Each formative assessment exemplar contains the following components:

1. Teacher Facing Information: This provides teachers with the full cluster as well as additional information including the question types, alignment to three dimensions, and answer key. Additionally, an example of a proficient student answer and a proficiency scale for all three dimensions are included to support the evaluation of the last item of the assessment.
2. Students Facing Assessment: This is what the student may see. It is in a form that can be printed or uploaded to a learning platform. (Exception: Questions including simulations will need technology to utilize during assessment.)

Accommodation Considerations:

Teachers should consider possible common ways to provide accommodations for students with disabilities, English language learners, students with diverse needs or students from different cultural backgrounds. For example, these accommodations may include: Providing academic language supports, presenting sentence stems, or reading aloud to students. All students should be allowed access to a dictionary.

Teacher Facing Information

Standard: BIO.4.3

Assessment Format: Printable or Online Format (Does not require students to have online access)

Phenomenon	
<p>The ancestral forms of stickleback fish are small ocean dwellers that sport heavy armor in the form of bony plates and spines projecting from the back and pelvis. However, in many freshwater populations, the ocean sticklebacks' fully formed pelvic girdle, with long spines, became greatly reduced.</p>	<p>Proficient Student Explanation of Phenomenon:</p> <p>Because the frequency of fossil stickleback with pelvic spines decreased over the 15,000-year time span, we can infer that pelvic spines did not provide an advantage to stickleback fish that had them. Because pelvic spines in living three-spined stickleback populations provide a defense against large predatory fish, we can infer that there probably were no predatory fish in the ancient lake. Dr. Bell and colleagues have found fossils of other fish in the quarry, but most of them were small species that could not eat stickleback fish.</p>
Cluster Task Statement	
<p>(Represents the ultimate way the phenomenon will be explained or the design problem will be addressed)</p> <p>In the questions that follow, you will analyze and interpret data collected from fossils of threespine stickleback fish as well as living populations to identify patterns that explain how the proportion of traits tend to increase or decrease over time.</p>	
Supporting Information	
<p>The threespine stickleback fish is a model organism for studying evolution. Three-spined sticklebacks are small fish that live in oceans, streams, and lakes across the northern hemisphere. The ancient or fossil forms of stickleback fish are small ocean dwellers that have heavy armor in the form of bony plates and spines projecting from the back and pelvis. Scientists have been able to study both well preserved fossils of ocean dwelling Sticklebacks as well as many ocean and freshwater varieties that exist today.</p> <p>In both ocean and freshwater environments, Stickleback fish have predators. Large predatory fish can be found in the ocean while smaller insect predators are found in freshwater habitats. Scientists hypothesize that different amounts of body armor make these small fish more or less protected against different types of predators. See the image below for examples of Stickleback predators.</p>	

Stickleback adaptations for surviving specific predators. Sticklebacks with spines are better adapted to survive large predators. Sticklebacks with small or reduced spines are better suited for surviving predation by insects.

Experiment One:

Specimens of sticklebacks were collected and treated with a solution of dye that stains bones red, thereby making pelvic structures much easier to see. Individuals were then categorized as having a **complete, reduced, or absent** pelvic girdle structure.

Complete: a pelvis with a full pelvic girdle and two pelvic spines. (Note that only the fish with a complete pelvis have pelvic spines.)

Reduced: a range of structures from a simplified girdle with no pelvic spines to an oval nub for a girdle.

Absent: no pelvic girdle and no spines.

Cluster Questions

Gather (fossil):
Cluster Question # 1
Question Type: Short answer (fill

Question 1:
Experiment One:

in the blank)

Addresses:

___x___ DCI

___x___ SEP: analyze and interpret data

___x___ CCC: scale, proportion, quantity

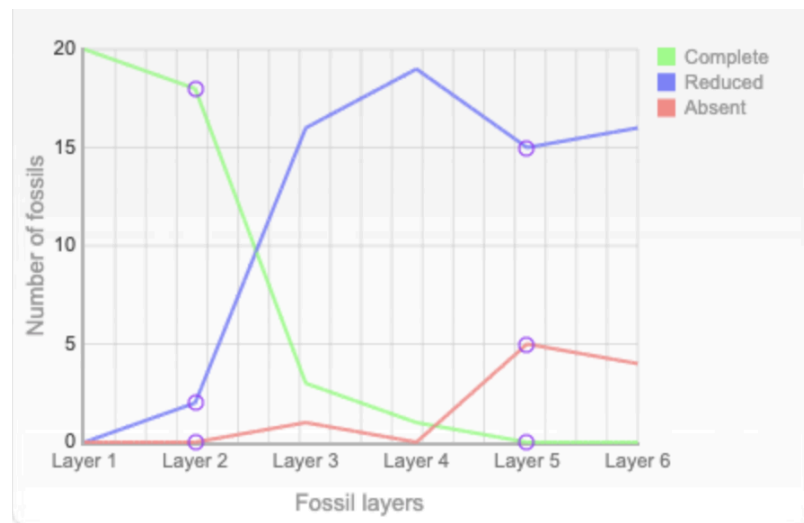

Answer:

Pelvic spines were more common in layer **2**. Layer 5 contained mostly fish **without** pelvic spines.

In this experiment, scientists characterized the pelvic structures of **fossil** stickleback fish from the Truckee Formation in Nevada—the site of a lake that existed about 10 million years ago. The fossils analyzed represent fish that lived in the lake at different time points spanning about 15,000 years.

Among the samples analyzed, layer 1 is the oldest. It coincides with a time when a population of sticklebacks with complete pelvic structures appeared in the lake. The next layers—2 to 6—are each spaced about 3,000 years apart, going from past to present.

Fossil Stickleback Pelvic Phenotype Totals						
	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6
Complete	20	18	3	1	0	0
Reduced	0	2	16	19	15	16
Absent	0	0	1	0	5	4

Based on the pelvic phenotypes measured, how do the fossils in layer 2 differ from those in layer 5?

Pelvic spines were more common in layer (2, 5). Layer 5 contained mostly fish (with, without) pelvic spines.

Question Type: Multiple Choice Reason (fossil):

Cluster Question # ___2___

Name: _____ Date: _____

Stimulus

The threespine stickleback fish is a model organism for studying evolution. Three-spined sticklebacks are small fish that live in oceans, streams, and lakes across the northern hemisphere. The ancient or fossil forms of stickleback fish are small ocean dwellers that have heavy armor in the form of bony plates and spines projecting from the back and pelvis. Scientists have been able to study both well preserved fossils of ocean dwelling Sticklebacks as well as many ocean and freshwater varieties that exist today.

In both ocean and freshwater environments, Stickleback fish have predators. Large predatory fish can be found in the ocean while smaller insect predators are found in freshwater habitats. Scientists hypothesize that different amounts of body armor make these small fish more or less protected against different types of predators. See the image below for examples of Stickleback predators.

Figure 1: Stickleback Adaptations

Stickleback adaptations for surviving specific predators. Sticklebacks with spines are better adapted to survive large predators. Sticklebacks with small or reduced spines are better suited for surviving predation by insects.

Figure 1 shows an image of two different stickleback fish and their predators.

Figure 2: Stickleback Pelvic Structure

Complete: a pelvis with a full pelvic girdle and two pelvic spines. (Note that only the fish with a complete pelvis have pelvic spines.)

Reduced: a range of structures from a simplified girdle with no pelvic spines to an oval nub for a girdle.

Absent: no pelvic girdle and no spines.

Figure 2 shows specimens of sticklebacks and the differences in their pelvic structure.

Specimens of stickleback fish were collected and treated with a solution of dye that stains bones red, thereby making pelvic structures much easier to see. Individuals were then categorized as having a **complete, reduced, or absent** pelvic girdle structure.

Your Task

In the questions that follow, you will analyze and interpret data collected from fossils of threespine stickleback fish as well as living populations to identify **patterns** that explain how the **proportion** of traits tend to increase or decrease over time.

Question 1

Investigation 1: In this investigation, scientists characterized the pelvic structures of **fossil** stickleback fish from the Truckee Formation in Nevada—the site of a lake that existed about 10 million years ago. The fossils analyzed represent fish that lived in the lake at different time points spanning about 15,000 years.

Among the samples analyzed, layer 1 is the oldest. It coincides with a time when a population of sticklebacks with complete pelvic structures appeared in the lake. The next layers—2 to 6—are each spaced about 3,000 years apart, going from past to present.

Table 1: Fossil Stickleback Pelvic Phenotype Totals

Fossil Stickleback Pelvic Phenotype Totals						
	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6
Complete	20	18	3	1	0	0
Reduced	0	2	16	19	15	16
Absent	0	0	1	0	5	4

Table 1 shows the number of fossil stickleback found in lake layers with various pelvic structures.

Graph 1: Fossil Stickleback Pelvic Phenotypes

Graph 1 shows the data from Table 1 in line graph form.

Based on the pelvic phenotypes measured, how do the fossils in layer 2 differ from those in layer 5?

Pelvic spines were more common in layer _____ (2, 5). Layer 5 contained mostly fish _____ (with, without) pelvic spines.

Question 2

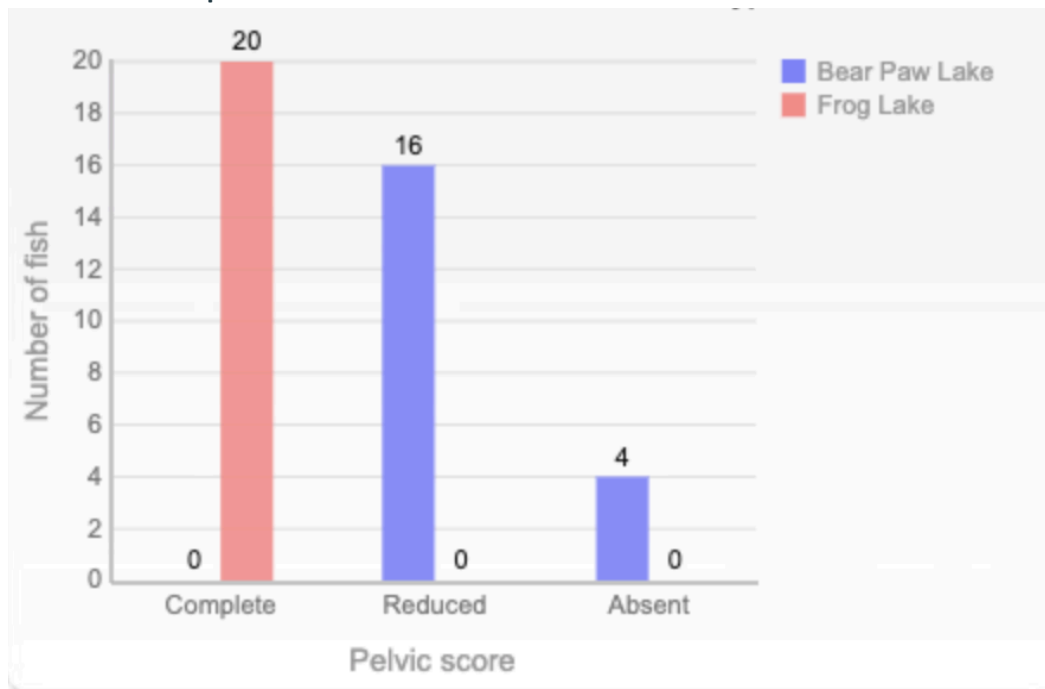

On the basis of the data from Table 1 and Graph 1, what do you predict would happen to the pelvic girdles of stickleback fish 10,000 years after the ones observed in experiment 1?

- A. They would become complete.
- B. They would become reduced.
- C. They would become absent.
- D. None of the above.

Question 3

Investigation 2: In this investigation, scientists scored 20 fish from Bear Paw Lake and 20 fish from Frog Lake. These lakes were originally inhabited by the same ocean population of stickleback but were separated into distinct environments thousands of years ago. Bear Paw lake is completely enclosed where Frog Lake is connected to other waterways by a small stream. With this connection Frog Lake is populated with large predatory fish, while Bear Paw has only freshwater insect predators.

Graph 2: Pelvic Structures of Stickleback Fish from Two Lakes

Graph 2 shows the data from the investigation of Bear Paw Lake and Frog Lake Stickleback fish populations.

Analyze the data from Investigation 2 to determine how the proportion of fish with complete pelvis and spines from Frog Lake compares to the proportion of complete pelvis fish in Bear Paw Lake?

- A. The proportions are essentially the same.
- B. The proportion of fish with complete pelvis have increased in Bear Paw Lake when compared to Frog Lake.
- C. The proportion of fish with complete pelvis structures have decreased in Bear Paw lake when compared to Frog Lake.
- D. The proportion of fish with absent pelvis structures are on the rise in Frog Lake.

Question 4

What evidence from Investigation 2 and the Stimulus background information could be used to determine why there is a difference in the proportion of fish with pelvic structures when comparing Frog Lake and Bear Paw Lake?

Question 5

Analyze the data from Investigation and draw conclusions about the impact of large predators and the effect they have on the presence or absence of Pelvic spines in Stickleback fish. Check all that apply.

- ☐ Pelvic spines protect sticklebacks from large predators.
- ☐ Sticklebacks without spines would be eaten more frequently by freshwater predators.
- ☐ The predators in the two lakes are different, which affects whether or not spines are an advantageous trait.
- ☐ The absence of spines provides no advantage with either predator.
- ☐ Having pelvic spines in Frog Lake protects Stickleback fish from being eaten by large predators.

Question 6

What can be inferred about the presence or absence of predatory fish when the Truckee Formation was a lake from Investigation 1? Describe the evidence.

Question 7

Using both Investigations 1 and 2 as a reference, make a prediction about what would happen to the proportion of fish with pelvic girdles in Bear Paw Lake after several generations? Support your claim with evidence of evolutionary patterns from both studies.
