

# **Fossils**

Fossils are the remains of plants and animals that lived long ago. This means that parts of some animals and plants didn't rot away after they died.

You can find fossils all over the world. Sometimes fossils tell scientists how the Earth has changed and how life was long ago.

Carnivores are dinosaurs that eat meat and herbivores are dinosaurs that eat plants. Dinosaur fossils have been found.

Body fossils are the bones of teeth and shells. Micro fossils are fossils that are really tiny. You have to use a microscope to see it close up.

Some fossils tell secrets about life here on earth and secrets from millions of years ago. Long ago the elephant looked more like a pig.

There are many different types of fossils right now. Paleontologists are looking for fossils and there might be new discoveries.
