Programmeringsuppgift

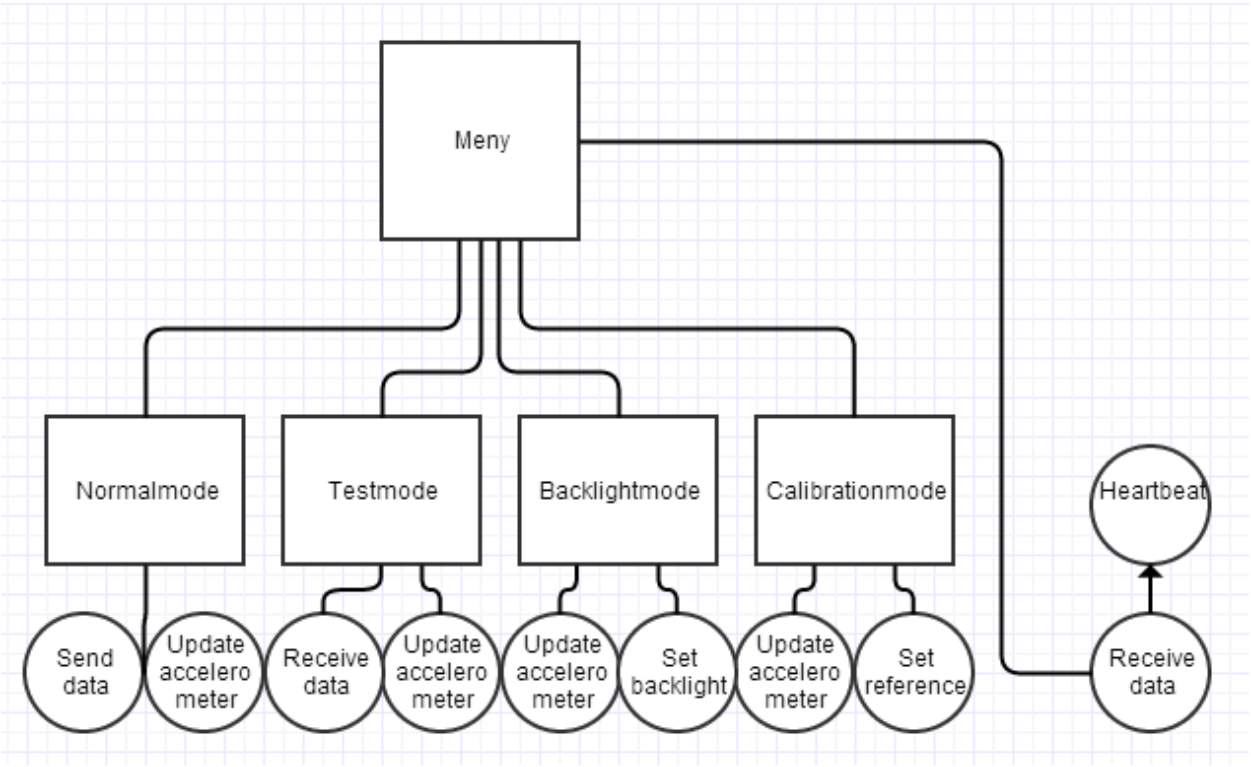
Tiltbaserad trådlös kontroll för radiobil

IE1206 - Inbyggd Elektronik

Karl Gäfvert
Rasmus Linusson

Produkt

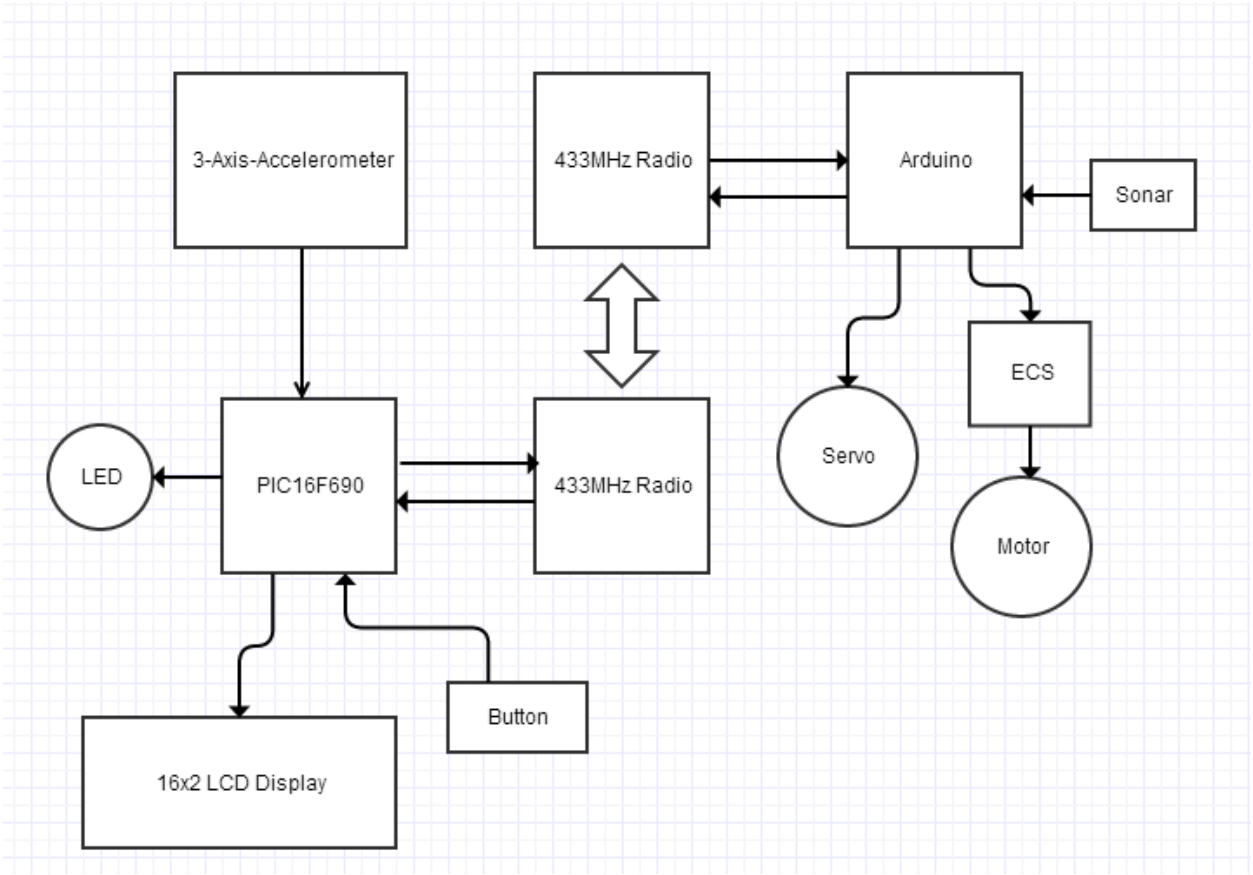
Kontroll som styr en radiostyrd leksaksbil genom att känna skillnader i lutning. Med hjälp av en accelerometer kan kontrollens orientering, eller lutning, beräknas. Dessa värden konverteras sedan till gas- och styrvärden som skickas med hjälp av en radiosändare till bilen. Bilen sänder samtidig information tillbaka till kontrollen med data från en sonar som sitter monterad längst fram på bilen. Kontrollen har en enkel meny som kontrolleras av en knapp. I menyn det går att byta mellan olika lägen, i dessa kan man, kalibrera utgångspositionen för kontrollen, bakgrundsljusstyrkan på LCD-displayen, ett testlägen som visar accelrometerns värden och referensvärden och ett normalläge där avståndet till närmasta objekt framför bilen presenteras tillsammans med en indikator som visar hur mycket bilen svänger och ett procentuellt värde över hur mycket användaren gasar. Kontrollen kan även känna om den är ansluten till bilen och indikera detta.



Beskrivning av funktionsprototyp

Vår funktionsprototyp består huvudsakligen av de hårdvarukomponeter som ilusteras på den vänstra sidan i blockdiagramet nedan. Den högra sidan beskriver komponeterna i bilen. Accelerometern beter sig som ett gyro när den tiltas och ger tre värden som analoga spänningar, två av dessa AD-omvandlas till 10-bitars heltal som sedan används för att beräkna gas och styrning. Så mäter alltså kontrollen lutningen på sig själv (breadboarden). PICen kommunicerar med radiomodulen med hjälp av sin inbyggda enhet för seriell kommunikation. Via radiomodulen skickas styr- och gasvärden till bilen i form av enkla kommandon som består av att först ett kommando och sedan ett värde skickas. PICen accepterar också inkommande data från radiomodulen med hjälp av en interrupt-rutin. Dessa data är distansvärdet som bilen skickar, det används även för att kontrollera anslutningen till bilen. En LCD-display med 2x16 tecken används för smart interaktion med användaren. På den skrivs menyer och värden beroende på hur användaren använder kontrollen. Förutom normalt läge och testläge går det att ställa bakgrundsbelysningen på LCD-displayen i en meny. Den generas av en PWM i PICen och sparas när kontrollen är avstängd i EEPROM. LCD-displayens kontrast ställs med en potentiometer. En enkel tryckknapp används för användaren ska kunna interagera med kontrollen och menyerna. Det finns också en grön LED som är tänd när kontrollen har en anslutning till bilen. Kontrollen strömförsörjs med hjälp av en 7-35V in, 5V 1A ut linjärregulator. Detta gör att kontrollen kan strömförsörjas med ett litet lätt 9V-batteri.

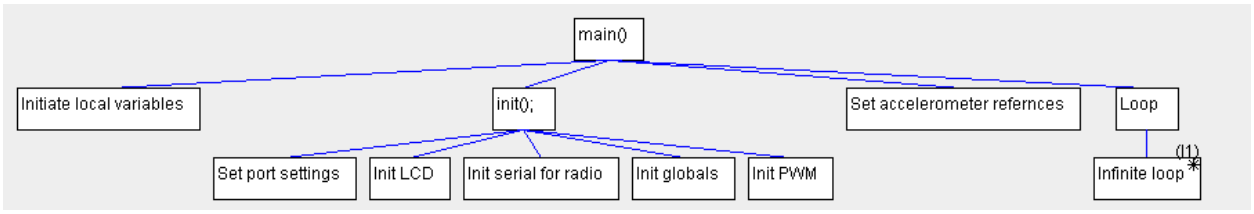
Diagram över kontrollen, bilen och hur de kommunicerar:

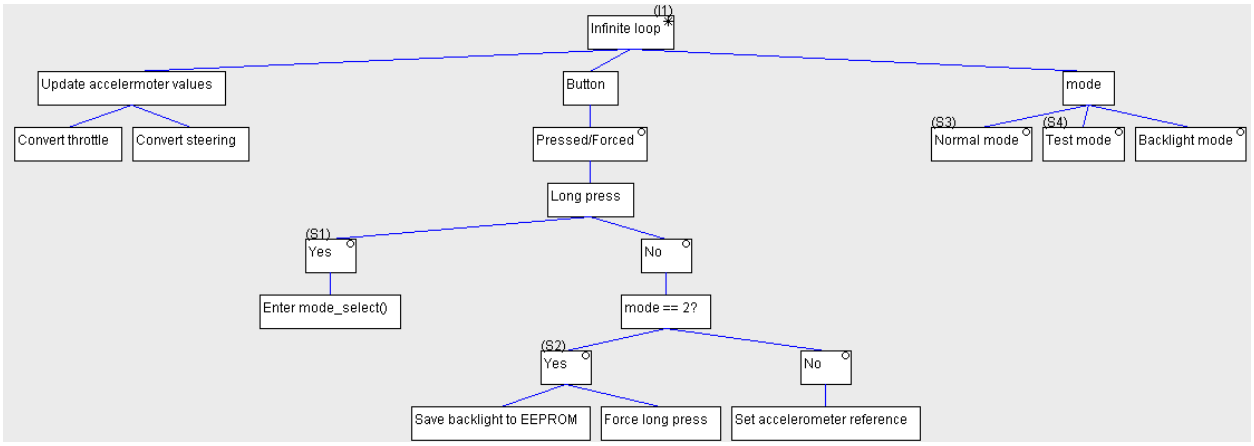


Checklista:

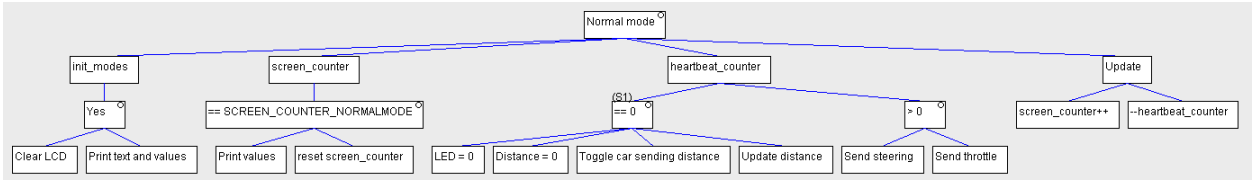
- **Meny**
  - Visar att menyn roterar vid kort klick
  - Visar att det går att komma till alla program i menyn vid långt klick
- **Testmode**
  - Visar att olika värden mottages från accelerometern och att dessa är lämpade för "simulera" ett gyroskop.
  - Kalibrering, kort tryck på knappen kalibrerar kontrollen till att utgå ifrån den orientering den har just nu.
  - Långt tryck återgår till menyn
- **Normalmode**
  - Sänder kommandon till bilen, vid tiltning åt något håll ska ge motsvarande önskad reaktion hos bilen.
  - Ett stapeldiagram på displayen som illusterar hur accelerometer-värden konverteras till något som går att tolka som styrning i höger och vänster.
  - En gas-mätare som visar hur mycket gas, med riktning, som ges till motorn.
  - Kalibrering, kort tryck på knappen kalibrerar kontrollen till att utgå ifrån den orientering den har just nu.
  - Heartbeat, visa hur kontrollen känner att bilen inte längre är kontaktbar och gröna LEDen slocknar och tänds igen när kommunikation återupprättats.
  - En distansmätare som visar avstånd till närmaste objekt framför bilen (upplösning: 0.2m ~ 10m)
  - Lågt tryck återgår till menyn
- **Backlightmode**
  - Tilta (höger-vänster) för att ändra duty cycle och backgrundsbelysningens styrka.
  - Tryck på knappen (spara).
  - Starta om, visa styrkan sparades i EEPROM och har samma värde nu.
- **Calibration mode**
  - Kalibrerar och återgå till menyn

Strukturdiagram:

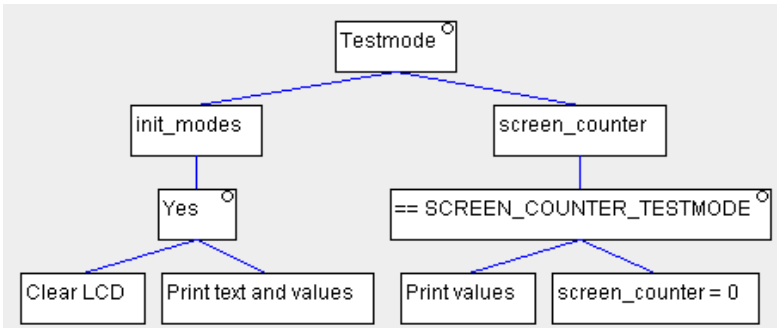




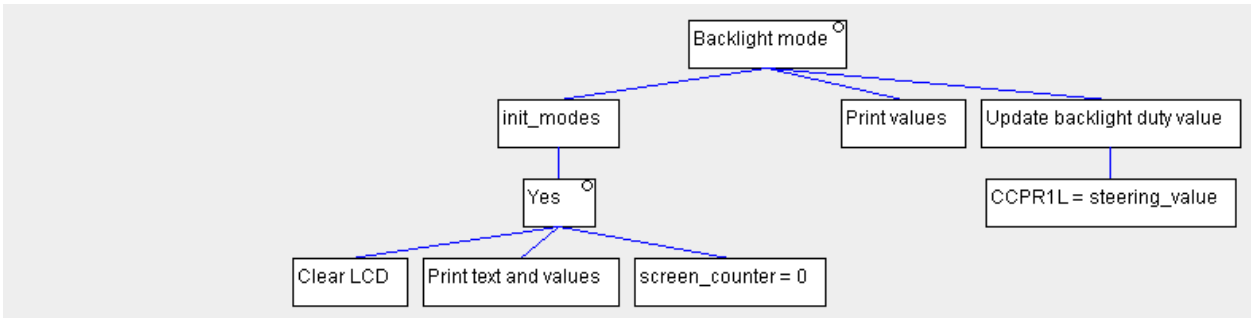
Mode - Normal



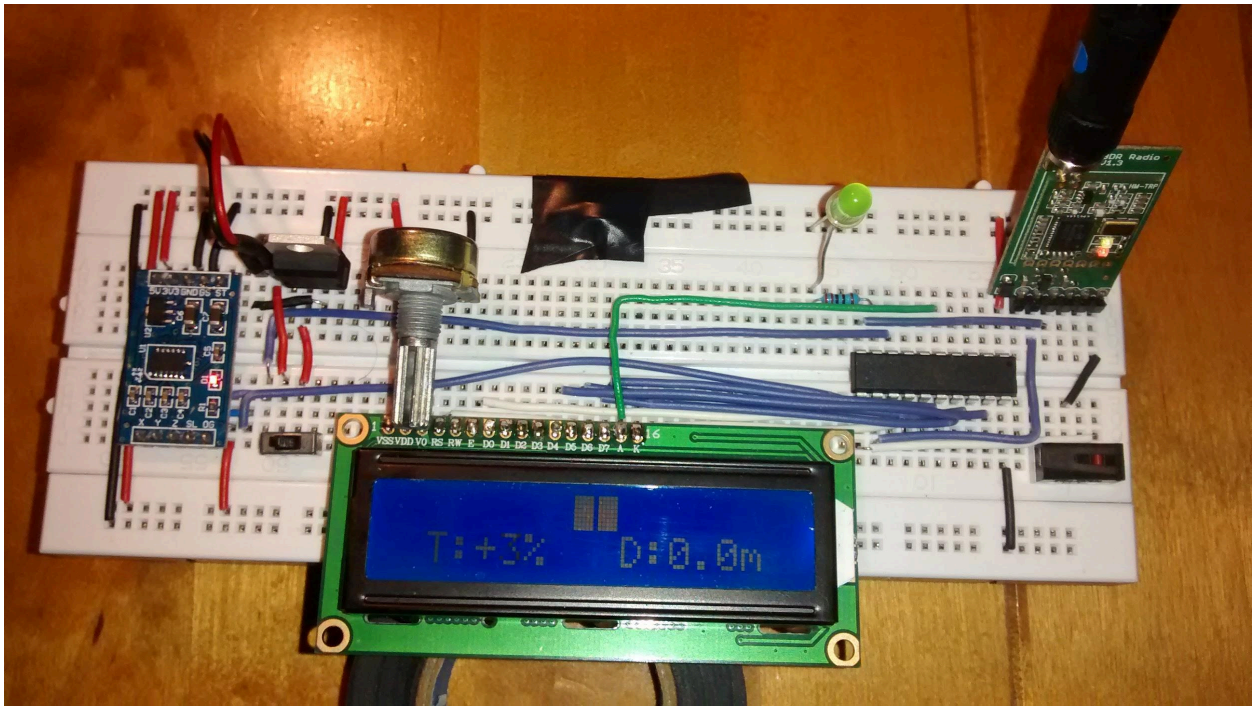
Mode - Test



Mode - Backlight



Då vi inte hade ett standard projekt eller standard komponenter har vi även bifogat ett foto av kopplingsdäcket.



Tejpat på baksidan sitter ett 9v-batteri.
