See this page in the course material.

Learning Outcomes

• Multiply binomials

Just like there are different ways to represent multiplication of numbers, there are several methods that can be used to multiply a binomial times a binomial.

Using the Distributive Property

We will start by using the Distributive Property. Look again at the following example.

We distributed the [latex]p[/latex] to get	[latex]x\color{red}{p}+3\color{red}{p}[/latex]
What if we have [latex]\left(x+7\right)[/latex]	
instead of [latex]p[/latex] ?	
Think of the [latex]x+7[/latex] as the	
[latex]\color{red}{p}[/latex] above.	
Distribute [latex]\left(x+7\right)[/latex] .	
Distribute again.	[latex]{x}^{2}+7x+3x+21[/latex]
Combine like terms.	[latex]{x}^{2}+10x+21[/latex]

Notice that before combining like terms, we had four terms. We multiplied the two terms of the first binomial by the two terms of the second binomial—four multiplications.

Be careful to distinguish between a sum and a product.

[latex]\begin{array}{cccc}\hfill \mathbf{\text{Sum}}\hfill & & & \hfill \mathbf{\text{Product}}\hfill \\ \hfill x+x\hfill & & & \hfill x\cdot x\hfill \\ \hfill 2x\hfill & & & \hfill {x}^{2}\hfill \\ \hfill \\ text{combine like terms}\hfill & & & \hfill \text{add exponents of like bases}\hfill \end{array}[/latex]

example

Multiply: [latex]\left(x+6\right)\left(x+8\right)[/latex]

Solution

	[latex]\left(x+6\right)\left(x+8\right)[/latex]
Distribute [latex]\left(x+8\right)[/latex] .	[latex]x\color{red}{(x+8)}+6\color{red}{(x+8)}[/lat
Distribute again.	[latex]{x}^{2}+8x+6x+48[/latex]
Simplify.	[latex]{x}^{2}+14x+48[/latex]

try it

See this interactive in the course material.

Now we'll see how to multiply binomials where the variable has a coefficient.

example

Multiply: [latex]\left(2x+9\right)\left(3x+4\right)[/latex]

Show Solution

Solution

	[latex]\left(2x+9\right)\left(3x+4\right)[/latex]
Distribute. [latex]\left(3x+4\right)[/latex]	[latex]2x\color{red}{(3x+4)}+9\color{red}{(3x+4)} [/latex]
Distribute again.	[latex] [latex]6{x}^{2}+8x+27x+36[/latex]
Simplify.	[latex]6{x}^{2}+35x+36[/latex]

try it

See this interactive in the course material.

In the previous examples, the binomials were sums. When there are differences, we pay special attention to make sure the signs of the product are correct.

example

Multiply: [latex]\left(4y+3\right)\left(6y - 5\right)[/latex]

Show Solution

Solution

	[latex]\left(4y+3\right)\left(6y - 5\right)[/latex]
Distribute.	[latex]4y\color{red}{(6y-5)}+3\color{red}{(6y-5)}[/
	latex]
Distribute again.	[latex]24{y}^{2}-20y+18y - 15[/latex]
Simplify.	[latex]24{y}^{2}-2y - 15[/latex]

try it

See this interactive in the course material.

Up to this point, the product of two binomials has been a trinomial. This is not always the case.

example

Multiply: [latex]\left(x+2\right)\left(x-y\right)[/latex]

Show Solution

Solution

	[latex](x+2)(x-y)[/latex]
Distribute.	[latex]x\color{red}{(x-y)}+2\color{red}{(x-y)}[/late

	x]
Distribute again.	[latex]x^2-xy+2x-2y[/latex]
Simplify.	There are no like terms to combine.

try it

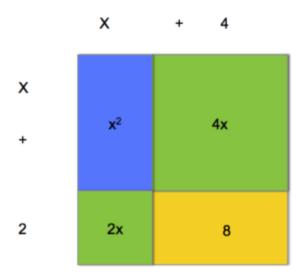

See this interactive in the course material.

Area Model for Multiplying Binomials

Now let's explore multiplying two binomials. For those of you that use pictures to learn, you can draw an area model to help make sense of the process. You'll use each binomial as one of the dimensions of a rectangle, and their product as the area.

The model below shows [latex]\left(x+4\right)\left(x+2\right)[/latex]:

Visual representation of multiplying two binomials.

Each binomial is expanded into variable terms and constants, [latex]x+4[/latex], along the top of the model and [latex]x+2[/latex] along the left side. The product of each pair of terms is a colored rectangle. The total area is the sum of all of these small rectangles, [latex]x^{2}+2x+4x+8[/latex], If you combine all the like terms, you can write the product, or area, as [latex]x^{2}+6x+8[/latex].

You can use the distributive property to determine the product of two binomials.

Example

Simplify. [latex]\left(x+4\right)\left(x+2\right)[/latex]

Show Solution

Distribute the [latex]x[/latex] over [latex]x+2[/latex], then distribute 4 over [latex]x+2[/latex].

[latex]x\left(x\right)+x\left(2\right)+4\left(x\right)+4\left(2\right)[/latex]

Multiply.

[latex]x^{2}+2x+4x+8[/latex]

Combine like terms [latex]\left(2x+4x\right)[/latex].

[latex]x^{2}+6x+8[/latex]

Answer

[latex]\left(x+4\right)\left(2x+2\right)=x^{2}+6x+8[/latex]

Look back at the model above to see where each piece of $[latex]x^{2}+2x+4x+8[/latex]$ comes from. Can you see where you multiply [latex]x[/latex] by [latex]x + 2[/latex], and where you get $[latex]x^{2}[/latex]$ from [latex]x + 2[/latex].

Another way to look at multiplying binomials is to see that each term in one binomial is multiplied by each term in the other binomial. Look at the example above: the [latex]x[/latex] in [latex]x+4[/latex] gets multiplied by both the [latex]x[/latex] and the [latex]2[/latex] from [latex]x+2[/latex], and the [latex]4[/latex] gets multiplied by both the [latex]x[/latex] and the [latex]x[/latex].

The following video provides an example of multiplying two binomials using an area model as well as repeated distribution.

Video Link

The Table Method

You may see a binomial multiplied by itself written as $[latex]{left(x+3\right)}^{2}[/latex]$ instead of $[latex]\left(x+3\right)\left(x+3\right)[/latex]$. To find this product, let's use another method. We will place the terms of each binomial along the top row and first column of a table, like this:

	[latex]x[/latex]	[latex]+3[/latex]
[latex]x[/lat ex]		
[latex]+3[/l atex]		

Now multiply the term in each column by the term in each row to get the terms of the resulting polynomial. Note how we keep the signs on the terms, even when they are positive, this will help us write the new polynomial.

	[latex]x[/latex]	[latex]+3[/latex]
[latex]x[/lat	[latex]x\cdot{x}=x	[latex]3\cdot{x}=+
ex]	^2[/latex]	3x[/latex]
[latex]+3[/l	[latex]x\cdot{3}=+	[latex]3\cdot{3}=
atex]	3x[/latex]	+9[/latex]
Now we can write the terms of the polynomial fr		

Now we can write the terms of the polynomial from the entries in the table:

[latex]\left(x+3\right)^{2}[/latex]

= [latex]x^2[/latex] + [latex]3x[/latex] + [latex]3x[/latex] + [latex]9[/latex]

= $[latex]x^{2}[/latex] + [latex]6x[/latex] + [latex]9[/latex].$

Pretty cool, huh?

Polynomials can take many forms. So far we have seen examples of binomials with variable terms on the left and constant terms on the right, such as this binomial [latex]\left(2r-3\right)[/latex]. Variables may also be on the right of the constant term, as in this binomial [latex]\left(5+r\right)[/latex]. In the next example, we will show that multiplying binomials in this form requires one extra step at the end.

Example

Find the product.[latex]\left(3-s\right)\left(1-s\right)[/latex]

Show Solution

Notice how the binomials have the variable on the right instead of the left. There is nothing different in the way you find the product. At the end we will reorganize terms so they are in descending order as a matter of convention.

[latex]\left(3-s\right)\left(1-s\right)[/latex]

Use a table this time.

	[latex]3[/late	[latex]-s[/lat
	x]	ex]
[latex]1[/late	[latex]3[/late	[latex]-s[/lat
x]	x]	ex]
[latex]-s[/lat	[latex]-3s[/la	[latex]s^2[/la
ex]		tex]

Notice how the *s* term is now positive. Collect the terms and simplify.

As a matter of convention, we will organize the terms so the one with greatest degree comes first. Pay close attention to the signs on the terms when you reorganize them. The [latex]3[/latex] is positive, so we will use a plus in front of it, and the [latex]4[/latex] is negative so we use a minus in front of it.

```
[latex]\begin{array}{c}\left(3-s\right)\left(1-s\right)\left(1-s\right)\left(3-s\right)\left(1-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left(3-s\right)\left
```

Answer

[latex]\left(3-s\right)\left(1-s\right)=s^2-4s+3[/latex]

Using FOIL to Multiply Binomials

Foil Crane

Remember that when you multiply a binomial by a binomial you get four terms. Sometimes you can combine like terms to get a trinomial, but sometimes there are no like terms to combine. Let's look at the last example again and pay particular attention to how we got the four terms.

[latex]\left(x+2\right)\left(x-y\right)[/latex]

 $[latex]{x}^{2}-\mathrm{int}{xy}+2x-2y[/latex]$

Where did the first term, [latex]{x}^{2}[/latex], come from?

```
It is the product of [latex]x\text{ and }x[/latex], the first terms in [latex]\left(x+2\right)\text{and}\left(x-y\right)[/latex].
```

The next term, [latex]-\mathit{\text{xy}}[/latex], is the product of [latex]x\text{ and }-y[/latex], the two **outer** terms.

The third term, [latex]+2x[/latex], is the product of [latex]2 and x[/latex], the two **inner** terms.

And the last term, [latex]-2y[/latex], came from multiplying the two **last** terms.

We can use a shortcut called the FOIL method when multiplying two binomials. Some people use the FOIL method to keep track of which pairs of terms have been multiplied when you are multiplying two binomials. This is not the same thing you use to wrap up leftovers, but an acronym for **First, Outer, Inner, Last.** It is called FOIL because we multiply the **f**irst terms, the **o**uter terms, the inner terms, and then the last terms of each binomial. The FOIL method arises out of using the distributive property to multiply two binomials. We are simply multiplying each term of the first binomial by each term of the second binomial and then combining like terms.

Let's go back to the example [latex] + (x+2) + (x-y) + (x-y)

When you add the four results, you get the same answer, [latex]x^{2}-xy+2x-2y[/latex].

The last step in multiplying polynomials is to combine like terms. In this example there were no like terms, but you will see this last step in several of the examples below. Remember that a polynomial is simplified only when there are no like terms remaining.

Caution! Note that the FOIL method only works for multiplying two binomials together. It will not work for multiplying a binomial and a trinomial, or two trinomials.

Example

Use FOIL to find the product. [latex](2x-18)(3x+3)[/latex]

Show Solution

Find the product of the first terms.

Find the product of the outer terms.

Find the product of the inner terms.

Find the product of the last terms.

 $\latex]\begin{array}{cc}6{x}^{2}+6x - 54x - 54\hfill & \text{Add the products}.\hfill \ 6{x}^{2}+\left(6x - 54x\right)-54\hfill & \text{Combine like terms}.\hfill \ 6{x}^{2}-48x - 54\hfill & \text{Simplify}.\hfill \end{array}[/latex]$

The following steps summarize the process for using FOIL to multiply two binomials. It is very important to note that this process only works for the product of two binomials. If you are multiplying a binomial and a trinomial, it is better to use a table to keep track of your terms.

Use the FOIL method for multiplying two binomials

- 1. Multiply the **First** terms.
- 2. Multiply the **Outer** terms.
- 3. Multiply the **Inner** terms.
- 4. Multiply the **Last** terms.

first last first last (a+b) (c+d)inner

5. Combine like terms, when possible.

outer

example

Multiply: [latex]\left(y - 8\right)\left(y+6\right)[/latex]

Show Solution

Solution

Step 1: Multiply the First terms.	
Step 2: Multiply the Outer terms.	
Step 3: Multiply the Inner terms.	
Step 4: Multiply the Last terms.	
Step 5: Combine like terms	[latex]y^2-2y-48[/latex]

try it

See this interactive in the course material.

example

Multiply: [latex]\left(2a+3\right)\left(3a - 1\right)[/latex]

Show Solution

Solution

	[latex](2a+3)(3a-1)[/latex]
Multiply the First terms.	
Multiply the Outer terms.	
Multiply the Inner terms.	
Multiply the Last terms.	
Combine like terms.	[latex]6a^2+7a-3[/latex]

See this interactive in the course material.

example

Multiply: [latex]\left(5x-y\right)\left(2x - 7\right)[/latex]

Show Solution

Solution

	[latex](5x-y)(2x-7)[/latex]
Multiply the First terms.	
Multiply the Outer terms.	
Multiply the Inner terms.	
Multiply the Last terms.	
Combine like terms. There are none.	[latex]10x^2-35x-2xy+7y[/latex]

See this interactive in the course material.

In the following video, we show an example of how to use the FOIL method to multiply two binomials.

Video Link

For another example of using the FOIL method to multiply two binomials watch the next video.

Video Link

Multiplying Two Binomials Using the Vertical Method

The FOIL method is usually the quickest method for multiplying two binomials, but it works *only* for binomials. You can use the Distributive Property to find the product of any two polynomials. Another method that works for all polynomials is the Vertical Method. It is very much like the method you use to multiply whole numbers. Look carefully at this example of multiplying two-digit numbers.

You start by multiplying [latex]23[/latex] by [latex]6[/latex] to get [latex]138[/latex].

Then you multiply [latex]23[/latex] by [latex]4[/latex], lining up the partial product in the correct columns.

Last, you add the partial products.

Now we'll apply this same method to multiply two binomials.

example

Multiply using the vertical method: [latex]\left(5x - 1\right)\left(2x - 7\right)[/latex]

Show Solution

Solution

It does not matter which binomial goes on the top. Line up the columns when you multiply as we did when we multiplied [latex]23\left(46\right)[/latex].

Multiply [latex]2x - 7[/latex] by [latex]-1[/latex] .	

Multiply [latex]2x - 7[/latex] by [latex]5x[/latex].	
Add like terms.	

Notice the partial products are the same as the terms in the FOIL method.

try it

See this interactive in the course material.

Order Doesn't Matter When You Multiply

One of the neat things about multiplication is that terms can be multiplied in either order. The expression [latex]\left(x+2\right)\left(x+4\right)[/latex] has the same product as [latex]\left(x+4\right)\left(x+2\right)[/latex], [latex]x^{2}+6x+8[/latex]. (Work it out and see.) The order in which you multiply binomials does not matter. What matters is that you multiply each term in one binomial by each term in the other binomial.

Let's look at another example using the FOIL method in which the variables have coefficients.

Example

Simplify [latex]\left(4x–10\right)\left(2x+3\right)[/latex] using the FOIL acronym.

Show Solution

 $[latex] begin{array}{l} text{First}:,,,,,,,4x left(2x right)=8x^{2} (Outer):,,,,4x left(3 right)=12 x (lnner):,,,,-10 left(2x right)=-20x (lnner):,,,,,-10 left(3 right)=-30 end{array}[/latex]$

Be careful about including the negative sign on the [latex]-10[/latex], since 10 is subtracted.

Combine like terms.

 $[latex]\begin{array}{c}\x^{2}+12x-20x-30\\text{}\=\x^{2}-8x-30\end{array}[/latex]$

Answer

 $[latex]\left(4x-10\right)\left(2x+3\right)=8x^{2}-8x-30[/latex]$

So far, we have shown several methods for multiplying two binomials together. Why are we focusing so much on binomials? They are one of the most well studied and widely used

polynomials, so there is a lot of information out there about them. In the previous example, we saw the result of squaring a binomial that was a sum of two terms. In the next example we will find the product of squaring a binomial that is the difference of two terms.

Example

Square the binomial difference [latex]\left(x-7\right)[/latex]

Show solution

Write the product of the binomial.

$[latex]{\left(x-7\right)}^2=\left(x-7\right)\left(x-7\right)[/latex]$

Let's use the table method, just because. Note how we carry the negative sign with the [latex]7[/latex].

]x[/lat	[latex]-7[/lat ex]
	[late	
]x[/lat	x]x^2[x]-7x[/
ex]	/latex]	latex]
[late	[late	[late
x]-7[/l	x]-7x[/	x]49[/l
atex]	latex]	atex]

Collect the terms, and simplify. Note how we keep the sign on each term.

 $[latex]\begin{array}{c}x^2-7x-7x+49\\text{}\=x^2-14x+49\end{array}[/latex]$

Answer

[latex]x^2-14x+49[/latex]

Caution! It is VERY important to remember the caution from the exponents section about squaring a binomial:

You can't move the exponent into a grouped sum because of the order of operations!!!!!

INCORRECT: [latex]\left(2+x\right)^{2}\neq2^{2}+x^{2}[/latex]

CORRECT: [latex]\left(2+x\right)^{2}=\left(2+x\right)\left(2+x\right)[/latex]

In the video that follows, you will see another examples of using a table to multiply two binomials.

Video Link

Further Examples

The next couple of examples show you some different forms binomials can take. In the first, we will square a binomial that has a coefficient in front of the variable, like the product in the first example on this page. In the second we will find the product of two binomials that have the variable on the right instead of the left. We will use both the FOIL method and the table method to simplify.

Example

Find the product. [latex]\left(2x+6\right)^{2}[/latex]

Show Solution

We will use the FOIL method.

 $[latex]\left(2x+6\right)^{2}=\left(2x+6\right)\left(2x+6\right)[/latex]$

Now you can collect the terms and simplify:

 $[latex]\begin{array}{c}4x^2+12x+12x+36\\text{}\=4x^2+24x+36\end{array}[/latex]$

Answer

[latex](2x+6)^{2}=4x^{2}+24x+36[/latex]

In the last example, we want to show you another common form a binomial can take, each of the terms in the two binomials is the same, but the signs are different. You will see that in this case, the middle term will disappear.

Example

Multiply the binomials. [latex]\left(x+8\right)\left(x-8\right)[/latex]

Show Solution

Add the terms. Note how the two x terms are opposites, so they sum to zero.

Answer

 $[latex]\ensuremath{left}(x+8\right)\ensuremath{left}(x-8\right)=x^{2}-64[/latex]$

Think About It

There are predictable outcomes when you square a binomial sum or difference. In general terms, for a binomial difference,

[latex]\left(a-b\right)^{2}=\left(a-b\right)\left(a-b\right)[/latex],

the resulting product, after being simplified, will look like this:

[latex]a²-2ab+b²[/latex].

The product of a binomial sum will have the following predictable outcome:

 $[latex]\end{tabular} = a^2+2ab+b^2[/latex].$

The product of a binomial sum and binomial difference of the same two monomial will have the following predictable outcome:

 $[latex]\ensuremath{\columnwidth{b}\columnwidth{b}\columnwidth{b}\columnwidth{c}\columnwidth{b}\columnwidth{c}$

Note that a and b in these generalizations could be integers, fractions, or variables with any kind of constant. You will learn more about predictable patterns from products of binomials in later math classes.

In this section we showed how to multiply two binomials using the distributive property, an area model, by using a table, using the FOIL method, and the vertical method. Practice each method, and try to decide which one you prefer.

Some of the forms a product of two binomials can take are listed here:

- [latex]\left(x+5\right)\left(2x-3\right)[/latex]
- [latex]\left(x+7\right)^{2}[/latex]
- [latex]\left(x-1\right)^{2}[/latex]
- [latex]\left(2-y\right)\left(5+y\right)[/latex]
- [latex]\left(x+9\right)\left(x-9\right)[/latex]
- [latex]\left(2x-4\right)\left(x+3\right)[/latex]

And this is just a small list, the possible combinations are endless. For each of the products in the list, using one of the two methods presented here will work to simplify.

Summary

Multiplication of binomials and polynomials requires an understanding of the distributive property, rules for exponents, and a keen eye for collecting like terms. Whether the polynomials are monomials, binomials, or trinomials, carefully multiply each term in one polynomial by each term in the other polynomial. Be careful to watch the addition and subtraction signs and negative coefficients. A product is written in simplified form if all of its like terms have been combined.
