

# CS193X: Web Programming Fundamentals

Spring 2017

Victoria Kirst  
([vrk@stanford.edu](mailto:vrk@stanford.edu))

# Schedule

## Today:

- Fetch
  - JSON
  - Fetch in an class
- Querying REST APIs
  - Form submission
  
- **HW4 out!**

GitHub repo for today's lecture examples:

<https://github.com/yayinternet/lecture17> / [live](#)

Loading data from files

# Loading data from a file

What if you had a list of URLs in a text file that you wanted to load as images in your web page?

Fetch API

# Fetch API

[fetch\(\)](#): Function to load resources in JavaScript

```
fetch(pathToResource)  
  .then(onResponse)  
  .then(onResourceReady);
```

***onResponse***:

- Return [response.text\(\)](#) from this function to get the resource as a string in ***onResourceReady***

***onResourceReady***:

- Gets the resource as a parameter when it's ready

# Fetch API

```
function onTextReady(text) {  
  // do something with text  
}
```

```
function onResponse(response) {  
  return response.text();  
}
```

```
fetch('images.txt')  
  .then(onResponse)  
  .then(onTextReady);
```

# Completed example

```
function onTextReady(text) {  
  const urls = text.split('\n');  
  for (const url of urls) {  
    const image = document.createElement('img');  
    image.src = url;  
    document.body.append(image);  
  }  
}
```

```
function onResponse(response) {  
  return response.text();  
}
```

```
fetch('images.txt')  
  .then(onResponse)  
  .then(onTextReady);
```

# Completed example

```
function onTextReady(text) {  
  const urls = text.split('\n');  
  for (const url of urls) {  
    const image = new Image();  
    image.src = url;  
    document.body.append(image);  
  }  
}
```

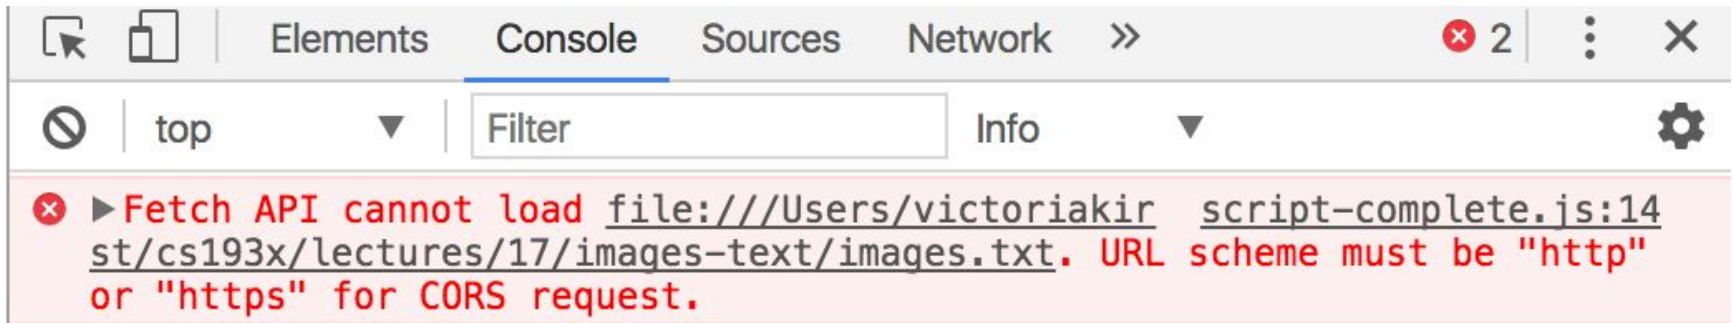

```
function onResponse(response) {  
  return response.text();  
}
```

```
fetch('images.txt')  
  .then(onResponse)  
  .then(onTextReady);
```

[Live example](#) /  
[GitHub](#)

# fetch() limitations

- You cannot fetch a resource that is hosted on file://
  - You must serve your resource over HTTP / HTTPS

# Serve over HTTP

We can run a program to serve our local files over HTTP:

```
$ python -m SimpleHTTPServer  
Serving HTTP on 0.0.0.0 port 8000 ...
```

This now starts up a **server** that can load the files in the current directory over HTTP.

- We can access this server by navigating to:  
<http://localhost:8000/>

# Note: Fetch Polyfill

Fetch is supported on [all major browsers](#), though Safari added support only within the last couple of months

- If you need to support older browsers, add a [Fetch Polyfill](#) the way we did with [Pointer Events](#)
- (We've done this for you in HW4 starter code)

JSON

# JavaScript Object Notation

**JSON:** Stands for **JavaScript Object Notation**

- Created by Douglas Crockford
- Defines a way of **serializing** JavaScript objects
  - **to serialize:** to turn an object into a string that can be deserialized
  - **to deserialize:** to turn a serialized string into an object

# JSON.stringify()

We can use the `JSON.stringify()` function to serialize a JavaScript object:

```
const bear = {  
  name: 'Ice Bear',  
  hobbies: ['knitting', 'cooking', 'dancing']  
};
```

```
const serializedBear = JSON.stringify(bear);  
console.log(serializedBear);
```

[CodePen](#)

# JSON.parse()

We can use the `JSON.parse()` function to deserialize a JavaScript object:

```
const bearString = '{"name":"Ice  
Bear","hobbies":["knitting","cooking","danci  
ng"]}';
```

```
const bear = JSON.parse(bearString);  
console.log(bear);
```

[CodePen](#)

# Fetch API and JSON

The Fetch API also has built-in support for JSON:

```
function onJsonReady(json) {  
  console.log(json);  
}
```

```
function onResponse(response) {  
  return response.json();  
}
```

```
fetch('images.json')  
  .then(onResponse)  
  .then(onJsonReady);
```

Return  
`response.json()`  
instead of  
`response.text()`  
and Fetch will  
essentially call  
`JSON.parse()` on the  
response string.

# Why JSON?

Let's say we had a file that contained a list of albums.

Each album has:

- Title
- Year
- URL to album image

We want to display each album in chronological order.

# Text file?

We could create a text file formatted consistently in some format that we make up ourselves, e.g.:

```
The Emancipation Of Mimi
```

```
2005
```

```
https://i.scdn.co/image/dca82bd9c1ccae90b09972027a408068f7a4d700
```

```
Daydream
```

```
1995
```

```
https://i.scdn.co/image/0638f0ddf70003cb94b43aa5e4004d85da94f99c
```

```
E=MC2
```

```
2008
```

```
https://i.scdn.co/image/bca35d49f6033324d2518656531c9a89135c0ea3
```

```
Mariah Carey
```

```
1990
```

```
https://i.scdn.co/image/02f12700d6c706e077e0e1e0d735e1552e0e0652
```

# Text file processing

We would have to write all this custom file processing code:

- Must convert numbers from strings
- If you ever add another attribute to the album, we'd have to change our array indices

```
function onTextReady(text) {  
  const lines = text.split('\n\n');  
  const albums = [];  
  for (let i = 0; i < lines.length; i++) {  
    const infoText = lines[i];  
    const infoStrings = infoText.split('\n');  
    const name = infoStrings[0];  
    const year = infoStrings[1];  
    const url = infoStrings[2];  
    albums.push({  
      name: name,  
      year: parseInt(year),  
      url: url  
    });  
  }  
  ...  
}
```

[Live example / GitHub](#)

# JSON file

It'd be much more convenient to store the file in JSON format:

```
{
  "albums": [
    {
      "name": "The Emancipation Of Mimi",
      "year": 2005,
      "url":
"https://i.scdn.co/image/dca82bd9c1ccae90b09972027a408068f7a4d700
"
    },
    {
      "name": "Daydream",
      "year": 1995,
      "url":
"https://i.scdn.co/image/0638f0ddf70003cb94b43aa5e4004d85da94f99c
"
    },
  ]
}
```

# JSON processing

Since we're using JSON, we don't have to manually convert the response strings to a JavaScript object:

- JavaScript has built-in support to convert a JSON string into a JavaScript object.

```
function onJsonReady(json) {  
    const albums = json.albums;  
    ...  
}
```

[Live example](#) /  
[GitHub](#)

Fetch in a class

# Discography page

Let's write a web page that lists the Mariah Carey albums stored in [albums.json](#) and lets us sort the albums: ([demo](#))

## Mariah Carey's albums

By year, descending

By year, ascending

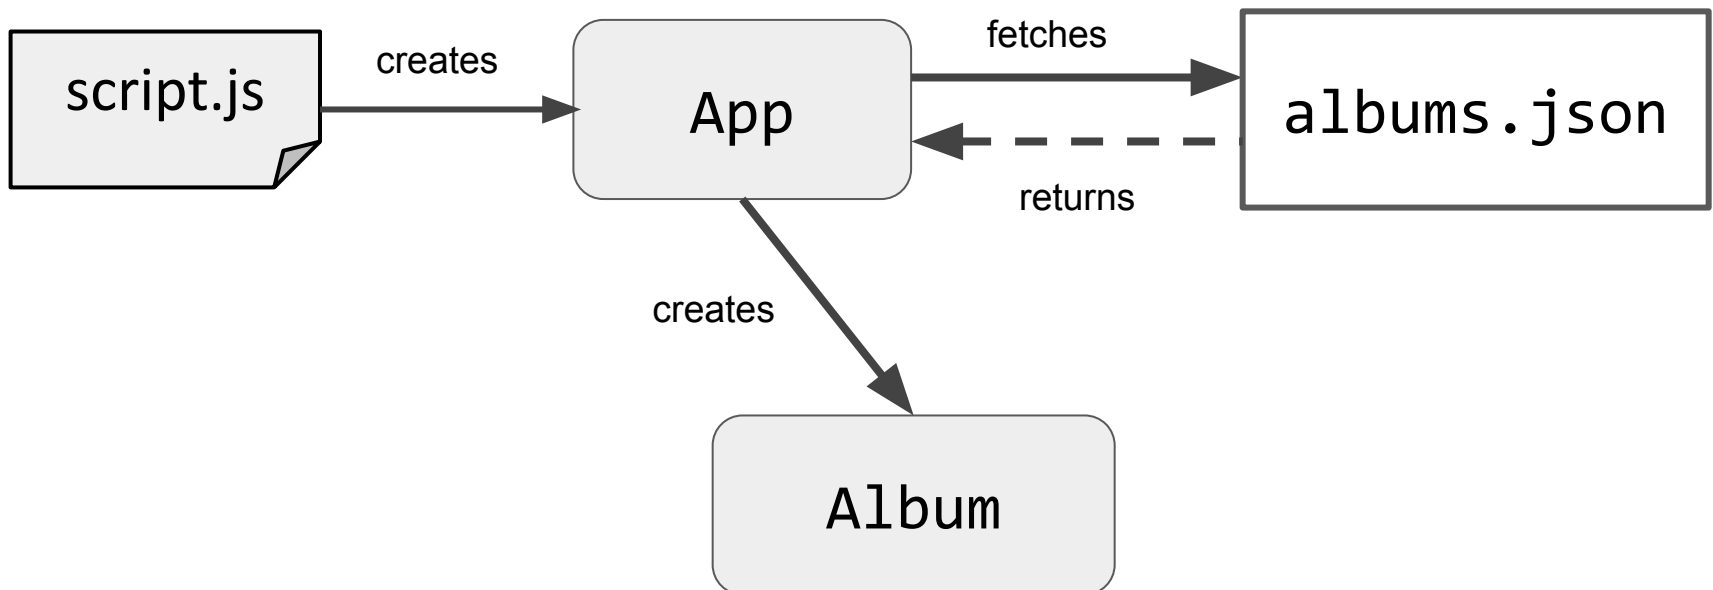

By title, alphabetical

# Class diagram

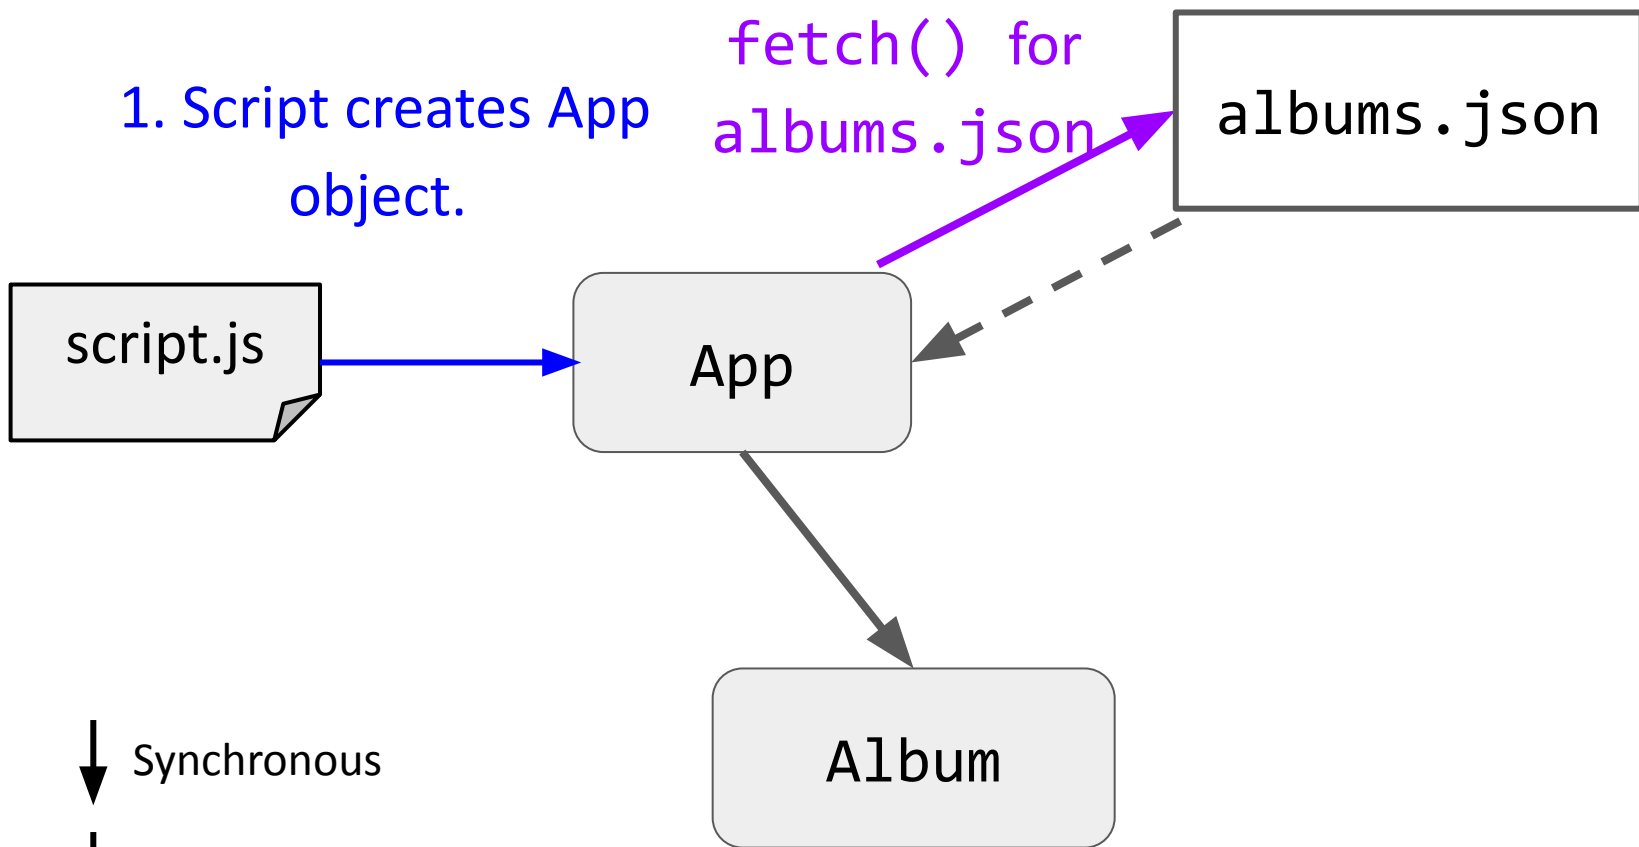

The class diagram is going to look something like this:

# Album fetch()

1. Script creates App object.

2. App calls fetch() for albums.json

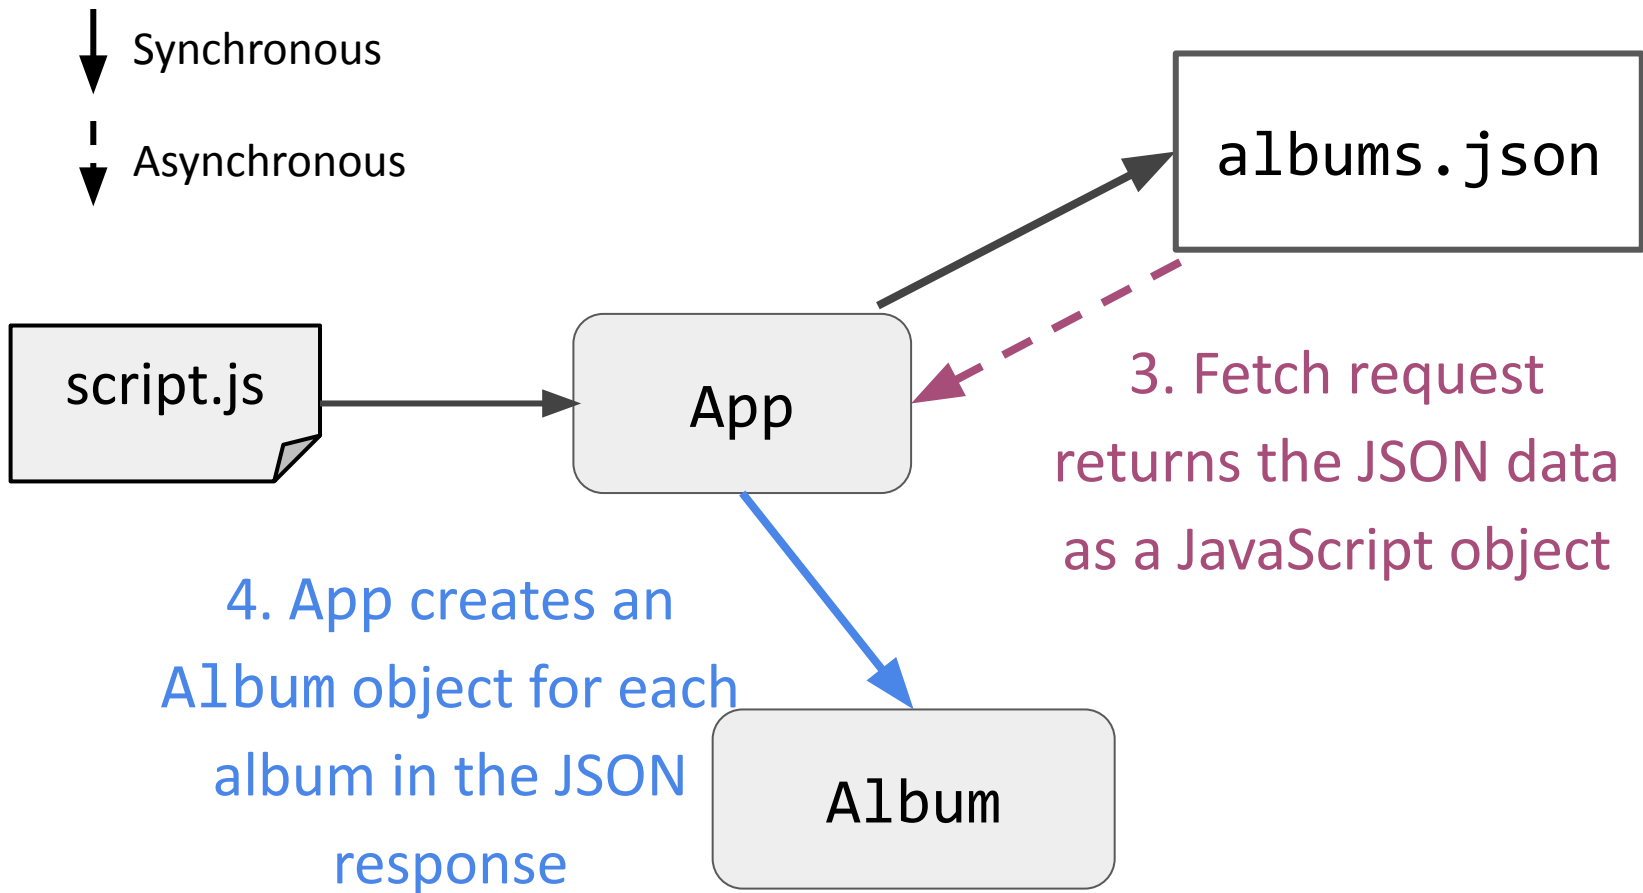

↓ Synchronous

- - - ↓ Asynchronous

# Album fetch()

↓ Synchronous

! ↓ Asynchronous

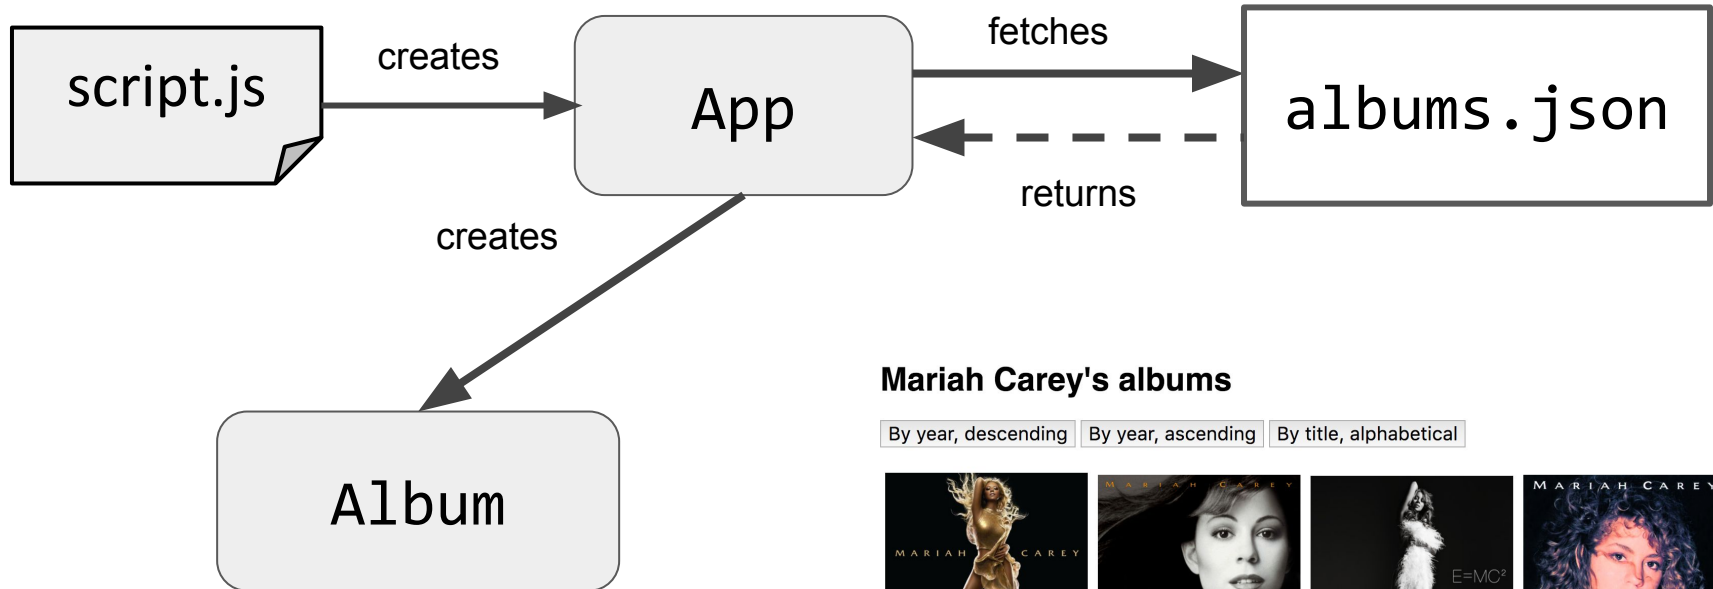

3. Fetch request returns the JSON data as a JavaScript object

4. App creates an Album object for each album in the JSON response

# Discography page

Q: How do we begin to implement this??

## Mariah Carey's albums

By year, descending | By year, ascending | By title, alphabetical

# Getting started

## Suggestion:

### Implement the Album class first!

- The App class will have to use the Album class, meaning it is dependent on the Album class.
- The Album class doesn't have any dependencies, so let's create that first.

[Starter](#)

# Milestone 1: Album

```
class Album {  
  constructor(containerElement, imageUrl) {  
    // Same as document.createElement('img');  
    const image = new Image();  
    image.src = imageUrl;  
    containerElement.append(image);  
  }  
}
```

For your first step, just implement the Album class: ignore `App/fetch()`/etc for now.

# Milestone 1: Album

Modify `script.js` to create two Albums.

```
const albumContainer = document.querySelector('#album-container');  
  
const album1 = new Album(  
  albumContainer,  
  'https://i.scdn.co/image/dca82bd9c1ccae90b09972027a408068f7a4d700');  
  
const album2 = new Album(  
  albumContainer,  
  'https://i.scdn.co/image/0638f0ddf70003cb94b43aa5e4004d85da94f99c');
```

# Milestone 1: Album

Milestone 1: [CodePen](#) / [page](#)

## Mariah Carey's albums

By year, descending

By year, ascending

By title, alphabetical

# Milestone 2: Print album info

## Suggestion: Implement the `fetch()` next!

- The `App` class is going to fetch data from `albums.json`, then it will create `Albums` based on that data.
- Let's implement `fetch()` first and make sure it works by printing out the results to the console.

Create a method `loadAlbums()` that calls `fetch()` like we did in the previous examples.

(Note: We don't have to define a constructor if we don't want to do in the constructor.)

```
class App {
  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady);
  }

  _onJsonReady(json) {
    const albums = json.albums;
    // Let's print the albums fetched.
    for (const album of albums) {
      console.log(album);
    }
  }

  _onResponse(response) {
    return response.json();
  }
}
```

# Milestone 2: Print album info

Modify `script.js` to create an `App` and call its `loadAlbums()` method.

```
// script.js
const app = new App();
app.loadAlbums();
```

# Milestone 2: Print album info

Milestone 2: [CodePen](#) / [page](#)

```
Console Clear ×  
  
Object {  
  name: "Rainbow",  
  url: "https://i.scdn.co/image/a666bcba51a0073ce34d7ad24703f4c45b374eff",  
  year: 1999  
}  
  
Object {  
  name: "Charmbracelet",  
  url: "https://i.scdn.co/image/c642f1ac7861c85133a0d4bc80a1ebefcad969a7",  
  year: 2002  
}  
  
Object {  
  name: "Memoirs Of An Imperfect Angel",  
  url: "https://i.scdn.co/image/c15ee84ece3ff03856ce0ec8112e7597b6c9d072",  
  year: 2009  
}  
>
```

# Milestone 3: Create Albums

## Now let's connect App and Album:

- The App class is supposed to create Albums based on the data fetched from the JSON file.
- Since Album and `fetch()` are working separately, now let's try making them work together.

```
class App {
  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady);
  }

  _onJsonReady(json) {
    const albums = json.albums;
    // Let's print the albums fetched.
    for (const album of albums) {
      console.log(album);
    }
  }

  _onResponse(response) {
    return response.json();
  }
}
```

```
class App {
  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady);
  }

  _onJsonReady(json) {
    const albums = json.albums;
    const albumContainer = document.querySelector('#album-container');
    for (const info of albums) {
      const album = new Album(albumContainer, info.url);
    }
  }

  _onResponse(response) {
    return response.json();
  }
}
```

# Milestone 3: Create albums

Milestone 3: [CodePen](#) / [page](#)

## Mariah Carey's albums

By year, descending

By year, ascending

By title, alphabetical

# Milestone 4: Sort by year, asc

**Let's now implement the Sort by Year, Ascending:**

- On button click:
  - Print to console
  - Unrender albums
  - Sort albums data
  - Rereunder albums

## **Mariah Carey's albums**

By year, descending

By year, ascending

By title, alphabetical

# Milestone 4: Sort by year, asc

```
class App {  
  constructor() {  
    const ascButton = document.querySelector('#asc');  
    ascButton.addEventListener('click', this._onAscClick);  
  }  
  
  _onAscClick() {  
    console.log('Clicked');  
  }  
  
  loadAlbums() {  
    fetch(JSON_PATH)
```

Start with adding an event handler and log to make sure it works: [CodePen](#)

Now we want to:

- Unrender the albums

```
class App {
  constructor() {
    const ascButton = document.querySelector('#asc');
    ascButton.addEventListener('click', this._onAscClick);
  }

  _onAscClick() {
    console.log('Clicked');
  }

  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady);
  }

  _onJsonReady(json) {
    const albums = json.albums;
    const albumContainer = document.querySelector('#album-container');
    for (const info of albums) {
      const album = new Album(albumContainer, info);
    }
  }
}
```

Now we want to:

- Unrender the albums

([CodePen](#))

```
class App {
  constructor() {
    const ascButton = document.querySelector('#asc')
    ascButton.addEventListener('click', this._onAscClick)
  }

  _onAscClick() {
    const albumContainer = document.querySelector('#album-container')
    albumContainer.innerHTML = ''
  }

  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady)
  }

  _onJsonReady(json) {
    const albums = json.albums
    const albumContainer = document.querySelector('#album-container')
    for (const info of albums) {
      const album = new Album(albumContainer, info)
    }
  }
}
```

Now we want to:

- Sort the albums data

Meaning we need the json.albums from the fetch request available in the onClick

```
class App {
  constructor() {
    const ascButton = document.querySelector('#asc')
    ascButton.addEventListener('click', this._onAscClick)
  }

  _onAscClick() {
    const albumContainer = document.querySelector('#album-container')
    albumContainer.innerHTML = ''
  }

  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady)
  }

  _onJsonReady(json) {
    const albums = json.albums;
    const albumContainer = document.querySelector('#album-container')
    for (const info of albums) {
      const album = new Album(albumContainer, info)
    }
  }
}
```

# Saving data from fetch()

We can save the data from the `fetch()` command in a field of the App class ([CodePen](#)):

```
_onJsonReady(json) {  
  this.albumInfo = json.albums;  
  const albumContainer = document.querySelector('#album-container');  
  for (const info of this.albumInfo) {  
    const album = new Album(albumContainer, info.url);  
  }  
}
```

But now we are using `this` in a callback... so...  
What do we need to do?

# Saving data from fetch()

We need to bind `_onJsonReady` in the constructor:

```
class App {  
  constructor() {  
    this._onJsonReady = this._onJsonReady.bind(this);  
  
    this.albumInfo = {};  
  
    const ascButton = document.querySelector('#asc');  
    ascButton.addEventListener('click', this._onAscClick);  
  }  
}
```

# Saving data from fetch()

We are now going to sort the album info on click ([CodePen](#)):

```
_onAscClick() {  
  const albumContainer = document.querySelector('#album-container');  
  albumContainer.innerHTML = '';  
  this.albumInfo.sort(function(a, b) {  
    return a.year - b.year;  
  });  
  console.log(this.albumInfo);  
}
```

But now we are using `this` in an event handler... so...  
What do we need to do?

# Saving data from fetch()

We need to bind `_onAscClick` in the constructor:

```
class App {  
  constructor() {  
    this._onJsonReady = this._onJsonReady.bind(this);  
    this._onAscClick = this._onAscClick.bind(this);  
  
    this.albumInfo = {};  
  
    const ascButton = document.querySelector('#asc');  
    ascButton.addEventListener('click', this._onAscClick);  
  }  
}
```

Last, we want to:

- Rerender the albums data

```
class App {
  constructor() {
    this._onJsonReady = this._onJsonReady.bind(this);
    this._onAscClick = this._onAscClick.bind(this);

    this.albumInfo = {};

    const ascButton = document.querySelector('#asc');
    ascButton.addEventListener('click', this._onAscClick);
  }

  _onAscClick() {
    const albumContainer = document.querySelector('#albumContainer');
    albumContainer.innerHTML = '';
    this.albumInfo.sort(function(a, b) {
      return a.year - b.year;
    });
    console.log(this.albumInfo);
  }

  loadAlbums() {
    fetch(JSON_PATH)
      .then(this._onResponse)
      .then(this._onJsonReady);
  }
}
```

# Rerender albums data

We can put the render code in a helper method and call it:  
([CodePen](#))

```
_onAscClick() {  
  this.albumInfo.sort(function(a, b) {  
    return a.year - b.year;  
  });  
  this._renderAlbums();  
}
```

```
_renderAlbums() {  
  const albumContainer = document.querySelector('#album-container');  
  albumContainer.innerHTML = '';  
  for (const info of this.albumInfo) {  
    const album = new Album(albumContainer, info.url);  
  }  
}
```

# Milestone 4: Sort by year, asc

Milestone 4: [CodePen](#) / [page](#)

## Mariah Carey's albums

By year, descending

By year, ascending

By title, alphabetical

# Milestone 5: Other buttons

Finally, let's implement the other two buttons:

## Mariah Carey's albums

By year, descending

By year, ascending

By title, alphabetical

Actually, the behavior is almost identical for each button, except the sort function...

# Add SortButton class

## Let's add a SortButton class

- The App class will create 3 SortButtons
- Each SortButton will take a sorting function as a parameter.

# Add SortButton class

We'll add and test the SortButton first... [CodePen](#)

```
class SortButton {
  constructor(containerElement, sortFunction) {
    this._onClick = this._onClick.bind(this);

    this.sortFunction = sortFunction;
    containerElement.addEventListener('click', this._onClick);
  }

  _onClick() {
    console.log('Sort clicked');
  }
}
```

# Sorting the albums

But then when we click a sort button, we want the Albums to be sorted... and the Albums are in the App class.

- **Q: How do we communicate between SortButton and App?**

# Sorting the albums

We can add an `onClickCallback` in the `SortButton` constructor (or fire a `CustomEvent`):

```
class SortButton {
  constructor(containerElement, onClickCallback, sortFunction) {
    this._onClick = this._onClick.bind(this);
    this.onClickCallback = onClickCallback;

    this.sortFunction = sortFunction;
    containerElement.addEventListener('click', this._onClick);
  }

  _onClick() {
    this.onClickCallback(this.sortFunction);
  }
}
```

# Sorting the albums

When constructing SortButton, pass it the `_sortAlbums` function.

```
class App {
  constructor() {
    this._onJsonReady = this._onJsonReady.bind(this);
    this._sortAlbums = this._sortAlbums.bind(this);

    this.albumInfo = {};

    const ascElement = document.querySelector('#asc');
    const ascButton = new SortButton(
      ascElement, this._sortAlbums, SORT_YEAR_ASC);
    const descElement = document.querySelector('#desc');
    const descButton = new SortButton(
      descElement, this._sortAlbums, SORT_YEAR_DESC);
    const alphaElement = document.querySelector('#alpha');
    const alphaButton = new SortButton(
      alphaElement, this._sortAlbums, SORT_ALPHA_TITLE);
  }

  _sortAlbums(sortFunction) {
    this.albumInfo.sort(sortFunction);
    this._renderAlbums();
  }
}
```

# Milestone 5: Completed!

Milestone 5: [CodePen](#) / [page](#) / [GitHub](#)

## Mariah Carey's albums

By year, descending

By year, ascending

By title, alphabetical

# Querying REST APIs

First: Servers again

# Servers

Sometimes when you type a URL in your browser, the URL is a **path to a file** on the internet:

- Your browser connects to the host address and requests the given file over **HTTP**
- The web server software (e.g. Apache) grabs that file from the server's local file system, and sends back its contents to you

**HTTP**: Hypertext Transfer Protocol, the protocol for sending files and messages through the web

# HTTP methods

**HTTP Methods:** the set of commands understood by a web server and sent from a browser

- **GET:** request/retrieve data  
This is request sent by the browser automatically whenever you navigate to a URL!
- **POST:** send/submit data
- **PUT:** upload file
- **PATCH:** updates data
- **DELETE:** delete data
- [More HTTP methods](#)

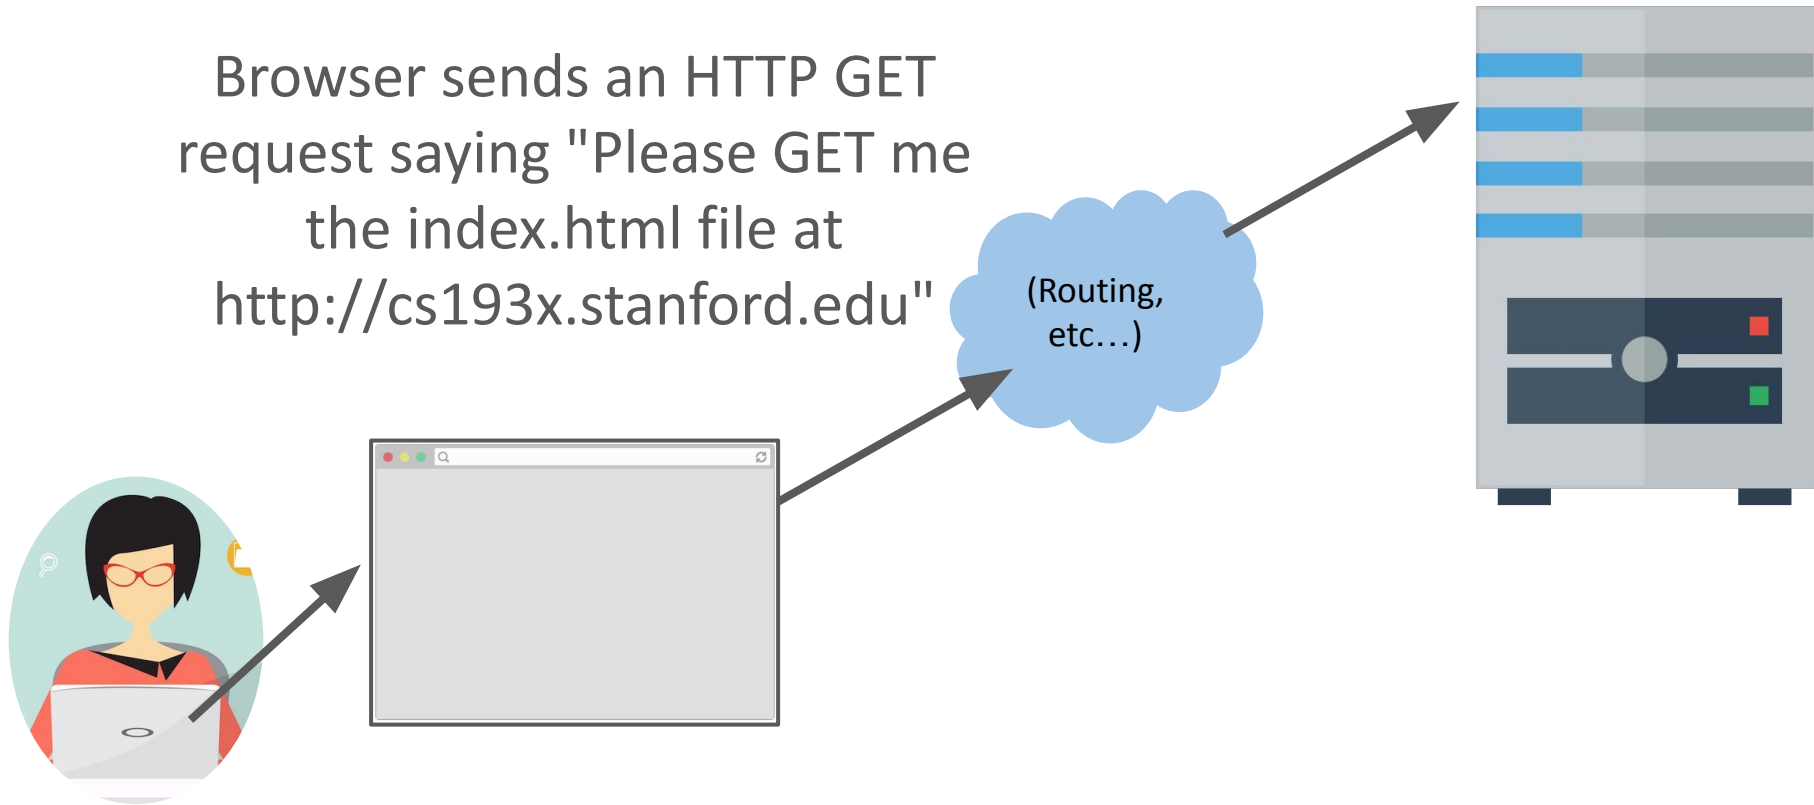

You type a URL in  
the address bar and  
hit "enter"

Server at  
`http://cs193x.stanford.edu`

Browser sends an HTTP GET  
request saying "Please GET me  
the index.html file at  
`http://cs193x.stanford.edu`"

**(Warning:** Somewhat inaccurate,  
massive hand-waving begins now.

See [this Quora answer](#) for slightly more detailed/accurate handwaving)

Server at  
<http://cs193x.stanford.edu>

Assuming all goes well, the server responds by sending the HTML file through the internet back to the browser to display.

# Servers

**Sometimes** when you type a URL in your browser, the URL is a **path to a file** on the internet:

- Your browser connects to the host address and requests the given file over **HTTP**
- The web server software (e.g. Apache) grabs that file from the server's local file system, and sends back its contents to you

**But that's not always the case.**

# Web Services

**Other times** when you type a URL into your browser, the URL represents **an API endpoint**, and not a path to a file.

That is:

- The web server does **not** grab a file from the local file system, and the URL is **not** specifying where a file is located.
- Rather, the URL represents a **parameterized request**, and the web server dynamically generates a response to that request.

# API endpoint example

Look at the URL for this [Google slide deck](#):

`https://docs.google.com/presentation/d/1Rim3-IXt6yN7yny_SBv7B5NMBiYbaQEiRMUD5s66uN8`

# API endpoint example

Look at the URL for this [Google slide deck](#):

`https://docs.google.com/presentation/d/1Rim3-IXt6yN7yny_SBv7B5NMBiYbaQEiRMUD5s66uN8`

- **presentation**: Tells the server that we are requesting a doc of type "presentation"
- **d/1Rim3-IXt6yN7yny\_SBv7B5NMBiYbaQEiRMUD5s66uN8**: Tells the server to request a doc ("d") with the document id of "1Rim3-IXt6yN7yny\_SBv7B5NMBiYbaQEiRMUD5s66uN8"

# RESTful API

**RESTful API**: URL-based API that has these properties:

- Requests are sent as an **HTTP request**:
  - **HTTP Methods**: GET, PUT, POST, DELETE, etc
- Requests are sent to **base URL**, also known as an "**API Endpoint**"
- Requests are sent with a specified **MIME/content type**, such as HTML, CSS, JavaScript, plaintext, JSON, etc.

# RESTful API

Almost every website on the internet uses RESTful URLs / RESTful APIs to handle requests to its servers.

Notable alternatives to REST:

- [GraphQL](#),
  - Used by Facebook since 2012
  - Open-sourced by Facebook since 2015
  - Still early but some big clients: GitHub, Pinterest
- [Falcor?](#)
  - Netflix's REST alternative, introduced ~2015
  - Probably cool but never hear of anyone using it
  - Doesn't even have a Wikipedia page

# Using REST APIs

# 3rd-Party APIs

Many websites expose REST APIs to outside developers. These are often called "**3rd-party APIs**" or "**Developer APIs**"

## Examples:

- Spotify
- Giphy
- GitHub
- Hoards of Google APIs
- Facebook
- Instagram
- Twitter
- etc...

Try Googling

"<product name> API"  
to see if one exists for  
a given company!

# Example: Spotify

Spotify has a [REST API](#) that external developers (i.e. people who aren't Spotify employees) can query:

Our Web API endpoints give external applications access to Spotify catalog and user data.

Web API Base URL: <https://api.spotify.com>

[User Guide](#) | [Tutorial](#) | [Code Examples](#)

Search:

METHOD	ENDPOINT	USAGE	RETURNS
GET	<a href="#">/v1/albums/{id}</a>	Get an album	album
GET	<a href="#">/v1/albums?ids={ids}</a>	Get several albums	albums
GET	<a href="#">/v1/albums/{id}/tracks</a>	Get an album's tracks	tracks*
GET	<a href="#">/v1/artists/{id}</a>	Get an artist	artist
GET	<a href="#">/v1/artists?ids={ids}</a>	Get several artists	artists
GET	<a href="#">/v1/artists/{id}/albums</a>	Get an artist's albums	albums*

# Example: Spotify

## REST API structure ([details](#)):

- The **Base URL** is `https://api.spotify.com`
- The **HTTP method** is `GET`
- The **API endpoint** to query is:  
`https://api.spotify.com/v1/albums/<spotify_id>`
- It returns **JSON data** about the album that's requested

Web API Base URL: `https://api.spotify.com`

METHOD	ENDPOINT
--------	----------

GET	<code>/v1/albums/{id}</code>
-----	------------------------------

---

# Example: Spotify

If we had Spotify Album ID 7aDBFWp72Pz4NZEtVBANi9, how would we make a GET request for the album information?

## REST API structure ([details](#)):

- The **Base URL** is `https://api.spotify.com`
- The **HTTP method** is GET
- The **API endpoint** to query is:  
`https://api.spotify.com/v1/albums/<spotify_id>`
- It returns **JSON data** about the album that's requested

# GET request: Browse to URL

Loading a URL in a browser issues an HTTP GET request for that resource.

So if we just piece together this URL:

- **API Endpoint:**

`https://api.spotify.com/v1/albums/<spotify_id>`

- **Album ID:** 7aDBFWp72Pz4NZEtVBANi9

- **Request URL:**

[https://api.spotify.com/v1/albums/7aDBFWp72Pz4NZE  
tVBANi9](https://api.spotify.com/v1/albums/7aDBFWp72Pz4NZEtVBANi9)

If you click on the link, you see it returns a JSON object.

# GET request: `fetch()`

Actually, the `fetch()` API also issues an HTTP GET request by default.

So if we do:

```
fetch('https://api.spotify.com/v1/albums/7aDBFWp72Pz4  
NZEtVBANi9')  
  .then(onResponse)  
  .then(onTextReady);
```

...we can load the JSON data as a JavaScript object, as we did with our `.json` files!

([CodePen](#) / [demo](#))

# Album example

Let's write a web page that asks the user to enter an artist's name, then displays the albums of that artist, as provided by the [Spotify Search API](#). ([live demo](#))

**Enter an artist:**

# Spotify search API

Spotify Search URL:

<https://api.spotify.com/v1/search?type=album&q=query>

E.g.

<https://api.spotify.com/v1/search?type=album&q=beyonce>

**Q: Hey, what's that at the end of the URL?**

- `?type=album&q=beyonce`

# Query parameters

You can pass parameters to HTTP GET requests by adding **query parameters** to the URL:

**?**type=album**&**q=beyonce

- Defined as key-value pairs
  - *param=value*
- The first query parameter starts with a **?**
- Subsequent query parameters start with **&**

# Reminder: HTML elements

Single-line text input:

```
<input type="text" />
```

hello

In JavaScript, you can read and set the input text via `inputElement.value`

Some other input types:

- [Select](#)
- [Textarea](#)
- [Checkbox](#)

# Form submit

Q: What if you want the form to submit after you click "enter"?

# Form submit

1. Wrap your input elements in a `<form>`

```
<form>  
  <input type="text" id="artist-text" />  
  <input type="submit" />  
</form>
```

You should also use `<input type="submit">` instead of `<button>` for the reason on the next slide...

# Form submit

2. Listen for the 'submit' event on the form element:

```
const form = document.querySelector('form');  
form.addEventListener('submit', this._onSubmit);
```

This is why you want to use `<input type="submit">` instead of `<button>` -- the 'submit' event will fire on click for but not `<button>`.

# Form submit

3. Prevent the default action before handling the event through `event.preventDefault()`:

```
_onSubmit(event) {  
  event.preventDefault();  
  const textInput = document.querySelector('#artist-text');  
  const query = encodeURIComponent(textInput.value);  
  
  this.albumUrls = [];  
  fetch(SPOTIFY_PATH + query)  
    .then(this._onResponse)  
    .then(this._onJsonReady);  
}
```

The page will refresh on submit unless you explicitly prevent it.

# Album example

Solution: [GitHub](#) / [Demo](#)

Enter an artist:
